Throughout 1944 quotations on imported tungsten ore and concentrates remained steady, but the price trend of domestic concentrates was downward. According to the Engineering and Mining Journal, Chinese, Bolivian, and Portuguese ore was quoted at \$24 a short-ton unit of WO_3 , duty paid; the price of domestic scheelite of good known analysis, in carlots, delivered, was \$26 a unit at the beginning of 1944 and was lowered to \$25 on May 25, to \$25.00–\$24.50 on August 31, to \$25.00–\$24.00 on September 14, and to \$24.50–\$24.00 on November 23. The average price for the domestic primary concentrates shipped in 1944, as reported to the Bureau of Mines, was \$23.36 a short-ton unit of WO_3 .

DOMESTIC PRODUCTION

The tungsten ores mined and milled in the United States, in general, contain 0.5 to 2.5 percent WO_3 and are beneficiated to a concentrate containing 60 percent or more WO_3 . Scheelite (calcium tungstate) is the tungsten mineral in most domestic ore mined. The three leading tungsten producers (66 percent of the United States total in 1944) and many small operators depend on ore carrying tungsten only as scheelite. Ferberite (iron tungstate), hübnerite (manganese tungstate), and wolframite (iron-manganese tungstate), in the order listed, contribute a comparatively small part of the tungsten in domestic ores. Most of the concentrates are converted to ferrotungsten and tungsten metal. Some high-purity scheelite concentrates, however, are charged directly to the steel bath. Wolframite is preferred for the filament in electric light bulbs.

The 4-year upward trend in production, which reached an all-time high of 12,055 (revised figure) short tons (60 percent WO_3 basis) of primary concentrates in 1943, turned downward to 10,259 tons in 1944. Although the concentrates were obtained from a large number of widely scattered operations in 12 States and Alaska, three States—California, Idaho, and Nevada—supplied 94 percent of the total, and four operators (United States Vanadium Corp., Bradley Mining Co., Nevada-Massachusetts Co., and Metals Reserve Company) produced 72 percent of the United States total. Idaho retained first place as the principal producing State, and the Bradley Mining Co. was again the chief operator.

In addition to the output of 10,259 tons of primary concentrates, 3,593 tons of secondary concentrates (15.53 percent WO_3), which require further milling, and some milling ore were produced in 1944. The bulk of these concentrates was shipped to the re-treatment plant of Metals Reserve Company at Salt Lake City, Utah; the ore was shipped to the re-treatment plant and to various purchasing depots of Metals Reserve Company. Some of the secondary concentrates shipped to the re-treatment plant in 1942, 1943, and 1944 were

treated during 1944, and the resultant primary concentrates recovered in 1944 are included in the production and shipment figures.

¹ Revised figures.

Alaska.—The Riverside mine near Hyder and the Stepovich mine near Fairbanks supplied the Alaskan production of tungsten in 1944. The Riverside mine produced 46 short tons of concentrates averaging 21.23 percent WO₃. These secondary concentrates, which were shipped to the re-treatment plant at Salt Lake City, Utah, for further treatment, are not included in the 1944 statistics. The low-grade concentrates produced at the Riverside mine in 1943 were remilled in 1944, and the tungsten values recovered are included in the 46 tons produced and shipped in 1944. Production at the Stepovich mine comprised 17 tons of primary concentrates averaging 64.27 percent WO₃ and 12 tons of secondary concentrates averaging 15.56 percent WO₃.

Arizona.—Production of primary tungsten concentrates in Arizona was 27 short tons averaging 53.3 percent WO₃ in 1944 compared with 60 tons averaging 55.03 percent WO₃ in 1943. Shipments were 32

sons averaging 54.31 percent WO_3 in 1944 and 65 tons averaging 57.29 percent WO_3 in 1943. The Black Gold and Las Guijas mines in Pima County, the Chloriding and Diff claims in Mohave County, the Maudina mine in Pinal County, and the Quartzite mine in Yuma County accounted for the bulk of the primary concentrates produced.

In addition to the primary tungsten concentrates produced and shipped in 1944, a small quantity of secondary concentrates was shipped to the re-treatment plant at Salt Lake City, Utah, and small quantities of milling ore were shipped to the Parker and Phoenix depots of Metals Reserve Company. The secondary concentrates and milling ore have been omitted from the 1944 statistics.

The tungsten deposits in the Boriana district and the Aquarius Range, Mohave County, have been described by Hobbs.³

California.—California again was the second-largest tungsten-producing State. Output of primary concentrates in 1944 was 2,912 short tons averaging 61 percent WO_3 compared with 3,559 tons averaging 65 percent WO_3 in 1943. Of the 1944 total, Inyo County supplied 68.7 percent; San Bernardino 11.7 percent; Tulare 7.5 percent; Madera 3.5 percent; and Fresno, Kern, Mono, and San Diego together 1.4 percent. The source of 7.2 percent was not reported, but the bulk came from Inyo and Tulare Counties.

Shipments of tungsten concentrates from California in 1944 totaled 2,940 short tons averaging 61.78 percent WO_3 compared with 3,569 tons averaging 65.07 percent WO_3 in 1943. The 1944 production and shipment figures include 106 tons of concentrates averaging 67.50 percent WO_3 , which were recovered at the Salt Lake City (Utah) re-treatment plant from the treatment of secondary concentrates originating in California, and 115 tons of concentrates averaging 45.28 percent WO_3 , which originated in California but were reshipped from the Salt Lake City plant without re-treatment. Although primary tungsten concentrates were shipped from a large number of widely scattered operations, five producers—United States Vanadium Corp. and Tungstar Corp. (in Inyo County), Hoefling Bros. (in San Bernardino County), Tulare County Tungsten Mines (in Tulare County), and Haggerty & Madden (in Madera County)—supplied 2,408 tons or 82 percent of the State total. The bulk of the remainder was shipped from the Salt Lake City plant; Tungsten Blue and Marble mines in Inyo County; Garnet Dike mine in Fresno County; and Harrel Hill mine in Tulare County.

In addition to the primary concentrates produced and shipped in 1944, 691 short tons of secondary concentrates averaging 16.63 percent WO_3 were shipped to the re-treatment plant at Salt Lake City for further treatment. A small quantity of milling ore was also shipped to the Salt Lake City plant, and small quantities of secondary concentrates and milling ore were shipped to the Fresno (Calif.) depot of Metals Reserve Company. The secondary concentrates and milling ore shipped to Salt Lake City and Fresno are not included in the 1944 statistics; instead, the resultant primary concentrates recovered are included.

The United States Vanadium Corp. continued to be the largest producer of primary concentrates in California. It operated the Pine Creek mine near Bishop and, in addition, treated some ore from the

³ Hobbs, S. W., *Tungsten Deposits in the Boriana District and the Aquarius Range, Mohave County, Ariz.*: Geol. Survey Bull. 940-I, 1944, 18 pp.

Adamson mine and some secondary concentrates from the Tungstar mine also near Bishop, the Yellow Pine mine in Idaho, and the Mill City mill in Nevada. The primary concentrates recovered from treating Yellow Pine and Mill City secondary concentrates have been credited in the statistics to Idaho and Nevada, respectively. Production of concentrates by the United States Vanadium Corp. was 35 percent less than in 1943.

The Tungstar mine near Bishop, operated by the Tungstar Corp. was the second largest producer in California in 1944. Production of primary and secondary concentrates was 65 percent more than in 1943. Sinking of a two-compartment shaft to 300 feet was in progress during 1944.

During 1944 Hoeft Bros. acquired the facilities of the Atolia Mining Co. to combine with its Spud Patch placer operation in San Bernardino County. Production of concentrates was 15 percent greater than in 1943.

The Atolia mine and mill in San Bernardino County, operated by the Atolia Mining Co.—the largest producer of tungsten concentrates during World War I—were shut down on March 20, 1944.

The Big Jim mine in Tulare County, operated by the Tulare County Tungsten Mines, produced at a greatly increased rate in 1944. Greater efficiency was attained by substituting electric power in the mill.

The Strawberry mine in Madera County, operated by Haggerty & Madden, produced 31 percent less concentrates than in 1943. A flotation unit was added to the mill in 1944.

Consolidated Tungsten, operating the Harrel Hill mine in Tulare County, produced 46 percent less concentrates than in 1943.

Colorado.—Production and shipments of primary concentrates (60 percent WO_3 basis) in Colorado were 299 and 296 short tons, respectively, in 1944 compared with 342 and 378 tons, respectively, in 1943. The 1944 production and shipment figures include 83 short tons of concentrates averaging 67.5 percent WO_3 , which were recovered at the Salt Lake City (Utah) re-treatment plant from the treatment of secondary concentrates originating in Colorado, and 25 tons of concentrates averaging 41.96 percent WO_3 , which originated in Colorado but were reshipped from the Salt Lake City plant without re-treatment.

In addition to the primary tungsten concentrates produced and shipped in 1944, Boulder Tungsten Mills (Inc.) and George H. Teal & Associates shipped 994 short tons of secondary concentrates averaging 6.85 percent WO_3 to the re-treatment plant of Metals Reserve Company at Salt Lake City, Utah, for further treatment. A substantial quantity of milling ore was shipped to the Nederland and Salida depots of Metals Reserve Company during 1944. These secondary concentrates and milling ore have been omitted from the 1944 statistics, but the resultant primary concentrates recovered are included.

Most of the primary tungsten concentrates produced in Colorado in 1944 came from operations of the Wolf Tongue Mining Co. and the Vanadium Corp. of America and from treating Colorado secondary concentrates at the Salt Lake City plant of Metals Reserve Company.

Idaho.—Idaho maintained its rank of leading producer of tungsten concentrates in the United States. However, production declined substantially in 1944 to 4,224 short tons averaging 56.21 percent WO_3 compared with 5,418 tons averaging 54.02 percent WO_3 in 1943. Shipments of primary concentrates in 1944 were 4,278 tons averaging

56.17 percent WO_3 compared with 5,186 tons averaging 53.78 percent WO_3 in 1943. The 1944 production and shipment figures include 558 tons of concentrates averaging 67.5 percent WO_3 , which were recovered at the Salt Lake City (Utah) plant from treating secondary concentrates originating at the Yellow Pine mine of Bradley Mining Co. The figures also include the concentrates recovered from treating Yellow Pine secondary concentrates at the plant of the United States Vanadium Corp. near Bishop, Calif.

The Yellow Pine mine near Stibnite, Valley County, operated by the Bradley Mining Co., was again the largest producer of tungsten concentrates in the United States. In 1944 it produced and treated 211,382 short tons of scheelite ore averaging 1.42 percent WO_3 , which yielded 3,428 tons of primary concentrates (53.60 percent WO_3) and 7,782 tons of secondary concentrates (8.40 percent WO_3). These secondary concentrates, which were shipped to the re-treatment plant at Salt Lake City, to the plant of the United States Vanadium Corp. near Bishop, Calif., and to the purification plant of the Bradley Mining Co. at Boise for further treatment, are not included in the 1944 statistics; instead, the resultant primary concentrates recovered are included. The Bradley Mining Co. completed a leaching plant at Boise for the purification of tungsten concentrates in 1944.

Production of hübnerite concentrates at the Ima mine in the Blue Wing district, Lemhi County, was 189 short tons (68.24 percent WO_3) in 1944 compared with 174 tons (60.53 percent WO_3) in 1943.

Missouri.—A small quantity of hübnerite (62 units of WO_3) was shipped from Madison County in 1944.

Montana.—The H. & H. Mines worked the gravel containing scheelite and gold in lower Henderson Creek near Hall, Granite County; 747 short tons of dredge concentrates averaging 1.7 percent WO_3 were treated, which yielded 15 tons of concentrates averaging 65 percent WO_3 .

Nevada.—Production and shipments of primary concentrates (reduced to an equivalent of 60 percent WO_3) were 2,747 and 2,665 short tons, respectively, in 1944 compared with 2,819 and 2,910 tons, respectively, in 1943. The 1944 production and shipment figures include 300 tons of concentrates averaging 67.5 percent WO_3 , which were recovered at the Salt Lake City (Utah) plant from treating Nevada secondary concentrates, chiefly from Getchell Mine Inc., and 100 tons of concentrates averaging 51.26 percent WO_3 , which originated in Nevada but were reshipped from the Salt Lake City plant without re-treatment. In addition, the concentrates recovered in California from treating Nevada secondary concentrates have been credited in the statistics to Nevada.

The Nevada-Massachusetts Co. and affiliated companies, operating mills at Mill City, Golconda, and Toulon, were the chief producers in Nevada in 1944, but output was 18 percent less than in 1943. The company Mill City mill, which was destroyed by fire on November 11, 1943, was rebuilt and began operating in 1944. Smaller but important producers of primary concentrates in 1944 were Nevada Scheelite, Inc., operating a mine of the same name in Mineral County; Tungsten Metals Corp., operating the Scheelite Chief, Oriole, Everitt, and Silver Bell mines, and the Cherry Creek Tungsten Mining Co., operating the Cherry Creek mine, all in White Pine County; and M. G. L. Mining Corp., operating the M. G. L. mine in Pershing County. The remaining production of primary concen-

trates in Nevada in 1944 came from a number of smaller operations, but the bulk was produced by Lincoln Mines, Inc., operating a mine of the same name in Lincoln County; Knowles Bros., operating the Star Tungsten mine, and Battle Creek Tungsten Co., operating the Battle Creek mine, both in Elko County; and the Gilded Age Mining Co., operating the Black Horse mine in White Pine County.

In addition to the primary tungsten concentrates produced and shipped in 1944, 1,814 tons of secondary concentrates averaging 19.88 percent WO_3 were shipped to the re-treatment plant at Salt Lake City, Utah, for further treatment. Much milling ore was also shipped to the Salt Lake City plant and to the Battle Mountain and Winnemucca depots of Metals Reserve Company. These secondary concentrates and milling ore have been omitted from the 1944 statistics, but the resultant primary concentrates are included. The bulk of these secondary concentrates was shipped from Getchell Mine, Inc. The remainder came chiefly from the Lincoln, Cherry Creek, Star Tungsten, and M. G. L. mines.

The flotation plant at Getchell Mine, Inc., treated 58,086 tons of ore averaging 0.59 percent WO_3 during 1944 and recovered 1,471 tons of concentrates averaging 17.75 percent WO_3 . The ore treated came from the company mines in Humboldt County and from the Richmond and Rose Creek mines in Humboldt and Pershing Counties, respectively, operated by W. C. Rigg, and the Riley mine in Humboldt County, operated by J. E. Riley. Tungsten mining and milling at Getchell Mine, Inc., were terminated on July 1 and June 20, 1944, respectively. The construction of a 200-ton concentrating mill, to be completed in March 1945 to treat ore from the Riley mine, was in progress in 1944.

New Mexico.—Alloy Metals, at its flotation mill near El Paso, Tex., recovered a small quantity of concentrates from ore mined at a property near Winston, Sierra County, N. Mex. A small quantity of milling ore was produced in New Mexico in 1944 and shipped to the Deming depot of Metals Reserve Company. This ore has been omitted from the 1944 statistics.

North Carolina.—Haile Mines, Inc., operating the Haile mines in Vance County, produced 321 tons of concentrates averaging about 35 percent WO_3 in 1944.

The tungsten deposits in Vance County have been described in some detail by Munds and others.⁴

South Dakota.—A small quantity of high-grade ore, produced by the Homestake Mining Co. in 1943, was shipped in 1944. The ore was produced at the Wasp No. 2 mine in Lawrence County. The O-F Exploration Co. recovered 2 tons of concentrates averaging about 50 percent WO_3 from a property near Keystone, Pennington County; no shipments were made, however.

Utah.—Production and shipments of high-grade tungsten concentrates in 1944 were each 10 short tons averaging 56 percent WO_3 , compared with 20 tons averaging 62 percent in 1943.

In addition to the tungsten concentrates produced and shipped in 1944, a substantial quantity of milling ore was shipped to the re-treatment plant at Salt Lake City for further treatment. This ore has been omitted from the 1944 statistics. Most of this ore was

⁴ Munds, W. H., Ewoldt, H. B., and Cohen, C. J., A Tungsten Find in North Carolina: Eng. and Min. Jour., vol. 145, No. 8, August 1944, pp. 80-81.

produced at the Desert mine in Juab County, Star Dust and Traction Lode mines in Tooele County, Lone Pine mine in Box Elder County, and Garnet mine in Beaver County.

The re-treatment plant of Metals Reserve Company at Salt Lake City suspended operations on April 30, 1944. During the 4 months it operated in 1944 it treated 6,870 tons of concentrates averaging 10.98 percent WO_3 . The plant feed comprised chiefly secondary concentrates from the Yellow Pine mine of Bradley Mining Co. The remainder was secondary concentrates from California, Colorado, and Nevada. The resultant primary concentrates produced and shipped during 1944 have been credited in the statistics to the State of origin. During 1944, 248 tons of concentrates averaging about 48 percent WO_3 , which had been shipped to the Salt Lake City plant for further milling, were reshipped without re-treatment; these concentrates originated in California, Colorado, Nevada, and Utah and have been credited in the statistics to the State of origin.

Washington.—Production and shipments of tungsten concentrates in Washington in 1944, were 5 and 4 short tons, respectively, averaging about 68 percent WO_3 , compared with 2 and 3 tons, respectively, in 1943. Output in 1944 came from the Deer Lake, Keith, and Germania mines.

FOREIGN TRADE ⁵

Domestic production is inadequate for requirements, and the United States imports both tungsten concentrates and products, chiefly the former. Receipts of imported ore and concentrates totaled 18,238,897 pounds (tungsten content), equivalent to 19,164 short tons of 60 percent WO_3 , in 1944, a slight decrease from the all-time record established in 1943. Although ore and concentrates were received from nine foreign countries in 1944, two—Bolivia (51 percent) and China (19 percent)—supplied 70 percent of the total.

Imports for consumption amounted to 18,396,284 pounds (tungsten content) in 1944, equivalent to 19,330 short tons of 60 percent WO_3 ; Bolivia, China, Argentina, and Brazil supplied 50, 20, 12, and 11 percent, respectively, of the total.

The duty on tungsten ore or concentrates is 50 cents per pound on the metallic tungsten contained therein. This is equivalent to \$7.93 per short ton unit.⁶

Exports of tungsten ore and concentrates from the United States are insignificant; none was exported in 1944 compared with 2,416 pounds in 1943.

Imports of tungstic acid were 21 pounds in 1944 compared with none in 1943. No tungsten metal, ferrotungsten, tungsten carbide, and other compounds of tungsten, or combination containing tungsten or tungsten carbide, were imported in 1943 and 1944.

Exports of metal, wire, shapes, and alloys other than ferrotungsten were 313,174 pounds in 1944 compared with 230,415 pounds in 1943. Exports of ferrotungsten were 2,353,340 pounds in 1944 compared with 1,032,649 pounds in 1943. Exports of sodium tungstate were 2,485 pounds in 1944 compared with 1,508 pounds in 1943. There were no exports of tungstic acid in 1944 compared with 51,703 pounds in 1943.

⁵ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

⁶ A unit, as applied to tungsten ores, is 1 percent of a ton of tungsten trioxide (WO_3). Thus, a short-ton unit is 20 pounds of WO_3 or 16.66 pounds of tungsten (W).

Tungsten ore and concentrates imported into the United States, 1943-44, by countries

¹ Comprises ore and concentrates received in the United States; part went into consumption during year and remainder entered bonded warehouses.

² Comprises ore and concentrates withdrawn from bonded warehouses during year (irrespective of time of importation) and receipts during year for consumption.

³ Bureau of Mines estimates that about 82 percent of the quantity of tungsten ore and concentrates (value not determined) credited to Peru by the U. S. Department of Commerce originated in Bolivia.

CONSUMPTION

Consumption of tungsten ore and concentrates in the United States was about 20,100 short tons (60 percent WO₃ basis) in 1944 compared with 20,300 tons in 1943. Of the total consumed in 1944, 11,800 tons or 59 percent were converted to ferrotungsten, the form in which most of the tungsten is introduced into steel. However, high-purity tungsten concentrates are charged directly to the steel bath; and 2,600 tons (13 percent of the total) were so used in 1944. Tungsten-metal powder and other tungsten products, chiefly the former, employed about 5,700 tons or 28 percent of the total ore and concentrates consumed in 1944. As shown in the following table, the production of tungsten-metal powder increased substantially in 1944 over 1943.

Production of specified tungsten products in the United States, 1943-44, in pounds

Product	1943		1944	
	Gross weight	Tungsten content	Gross weight	Tungsten content
Ferrotungsten.....	¹ 13,876,000	¹ 10,891,583	13,391,658	10,264,824

¹ In addition to countries listed, tungsten ore is produced in Japan, U. S. S. R., and Western Australia, but data on production are not available. ² Data not available.

³ January to September, inclusive.

⁴ January to June, inclusive.

⁵ Less than 1 ton.

⁶ Estimate.

Argentina.—Argentina ranks second to Bolivia as a producer of tungsten in South America, but its place is being threatened by Brazil. Output in Argentina comes principally from San Luis and Córdoba Provinces; much smaller amounts are produced in San Juan, Catamarca, Mendoza, and La Rioja. Production was 2,262 and 2,200 metric tons (66 percent WO_3), respectively, in 1944 and 1943.

Bolivia.—Bolivia continues to be the largest tungsten producer in South America. Most of the deposits are in the Departments of La Paz, Oruro, Potosí, and Cochabamba. Output (as indicated by exports) was 7,935 and 6,902 metric tons (60 percent WO_3 basis), respectively, in 1944 and 1943.

Brazil.—Brazil became an important producer of tungsten in 1943 as a result of the discovery, early in 1942, of deposits of scheelite in the States of Paraíba and Rio Grande do Norte. Exports were 1,989 metric tons (67 percent WO_3) in 1944 and 1,167 tons (about 65 percent WO_3) in 1943. The scheelite deposits have been described by Johnston and De Vasconcellos.⁷ The following paragraphs are quoted from this article.

As all of the work to date consists of trenches and open cuts in surface material in which both residual and primary ore are mined, there are little data at hand about either the size or grade of the ore bodies. In several of the larger mines, ore zones have been traced along the strike of calcareous beds for a distance of 1 km. (0.6 mi.) or more. In these larger mines a pattern of ore shoots appears to be developing. Certainly, experience to date indicates that the ore bed varies greatly in its scheelite content as it is traced along the strike. The only quantitative data at hand are from Dr. Sandoval Carneiro de Almeida's exploration of the Monito mine. He found that in 20 trenches across the ore zone about 10 percent of the lineal distance was through material yielding more than 1.8 kilos (4.0 pounds) of scheelite per ton, 15 percent was through material yielding 1.1 to 1.8 kilos (2.4 to 4.0 pounds) per ton, and the remainder yielded less than 1.1 kilos (2.4 pounds) per ton. From ultra-violet lamp examinations of the hard ore of the larger mines, we formed the impression that most of the primary ore in the region contained less than 0.5 percent WO_3 , although some small pockets containing, perhaps, up to 1.5 percent WO_3 were seen. In some mines, however, there is a surface blanket enriched by residual concentration of scheelite. The grade of the concentrates ranges from 70 to 75 percent WO_3 , depending upon how well the material has been washed. In the final hand panning, losses are high.

All mining and milling is by hand methods. * * * Such hand methods are, of course, both wasteful and expensive and are possible with the low grade ores of the region only because of the low wage scale in relation to the present price of tungsten. Recently the Bodó mine has installed a small crushing plant for hard primary ore and table and jigs are on order.

At least 60 scheelite localities have been discovered in Paraíba and Rio Grande do Norte since early 1942, and new discoveries continue to be made. Present known localities are distributed throughout an area of about 15,000 square kilometers (9,300 square miles), and a similar geological environment extends over a large part of these two States whose combined area is more than 100,000 square kilometers (62,100 square miles). As the ultra-violet lamp was not introduced into the field until July 1943, most of these deposits were discovered without that aid. With the present production experience, more and more men in the area have learned to recognize scheelite and how to prospect for it. It is to be expected, therefore, that discoveries will continue to be made and it is very possible that better mines than those now known will be found.

China.—Production of tungsten declined to 3,235 metric tons in 1944 from 8,973 and 11,897 tons, respectively, in 1943 and 1942; the WO_3 content was not stated, but presumably it averaged about 70 percent. The reduced production in 1944 compared with 1943 was attributed primarily to the high cost of mining and to the loss of Hunan and Kwangsi Provinces to the enemy. Exports were 7,703

⁷ Johnston, W. D., Jr., and De Vasconcellos, F. M., Scheelite in Northeastern Brazil: Econ. Geol., vol. 40, No. 1, January-February 1945, pp. 34-60.

metric tons in 1944 compared with 10,320 and 7,392 tons, respectively, in 1943 and 1942.

Peru.—The first result of the Peruvian Government's effort to promote scientific exploitation of the country's mineral deposits is a 30-ton tungsten concentrator now operating near Callao.⁸ The flotation mill was designed in the ore-dressing laboratories of the newly founded Institute of Mining Engineering, maintained by the Government. Through this agency much encouragement has been given miners of strategic minerals in Peru, among them those working tungsten deposits in the Departments of Ancash and La Libertad and in the Provinces of Pallasca, Cabana, and Santiago de Chuco.

Production of tungsten in Peru was 584 metric tons (60 percent WO_3 basis) in 1944 compared with 722 tons in 1943 and with an average of 209 tons during the 5 years 1937–41.

Portugal.—As a result of greatly increased demand and competitive buying by the Allies and Germany, production of tungsten in Portugal advanced from 3,851 metric tons (60 percent WO_3 basis) in 1939 to 7,477 tons in 1943. However, on the eve of the invasion (June 6, 1944) of France by the Allies, Portugal prohibited the exportation of tungsten to Germany and, moreover, suspended the operation of existing mines and the development of new ones. Consequently, production of tungsten declined substantially; it was 4,088 tons during the first nine months of 1944.

Spain.—Production and disposition of tungsten in Spain have attracted much attention during World War II. Although a small tungsten producing country before the war, enormously increased demand and competitive buying by the Allies and Germany resulted in the opening of many new mines, most of which could not operate profitably except during wartime. As a consequence, reported production increased from 415 metric tons (60 percent WO_3 basis) in 1941 to 3,902 tons in 1943. Moreover, in Portugal quotations rose far above the price fixed in Spain, which led to extraordinary contraband activity. According to the Metal Bulletin:⁹

In the Spring of 1941 some 5,000 persons were illegitimately mining wolfram ore in the provinces of Cáceres and Salamanca adjacent to Portugal. There was also widespread contraband and wasteful exploitation in Galicia. Steps were taken to put an end to this by strict measures. * * * Between January and September 1942 the registered production rose from 50½ metric tons to 224½ tons monthly, making a nine months' total of 1,114 tons, whilst the probable illegal production fell from 202½ tons to 28½ tons a month making a total, however, of 1,163 tons of illegal output.

With the imposition of an embargo on petroleum by the Allies in February 1944, Spain suspended all exports of tungsten. In May 1944, exports to Germany were resumed on a limited basis, by agreement with the Allies, and the petroleum embargo was lifted. However, all exports of tungsten to Germany by land were stopped in August when the French border was closed to traffic. For these reasons, production of tungsten in Spain declined to 2,080 metric tons in 1944. At the close of 1944 only a few tungsten mines remained active as compared with 40 or 50 that were producing at the height of the tungsten boom.

SUMMARY

Bauxite and aluminum production and consumption declined substantially during 1944 as the result of cut-backs, decreased requirements, and growing stocks. Domestic mine production of crude bauxite decreased 54 percent from the record output of the previous year, totaling 3,721,135 short tons (3,162,571 tons, dried equivalent) compared with 8,156,551 tons (6,980,829 tons, dried equivalent) in 1943. Cancellation and termination of contracts between Metals Reserve Company and many mine operators and voluntary production decreases by other operating companies caused a drop in the annual rate of output to only 1,450,000 tons by the end of 1944. Stocks at consumers' plants dropped from 1,706,113 tons to 835,530 during the year, and mine stocks declined slightly from 542,100 tons on January 1 to 528,700 tons on December 31. Imports of bauxite decreased 64 percent and totaled 627,716 tons, a smaller quantity than in any year since 1939; a comparable drop was registered in exports, which fell 65 percent and totaled 164,234 tons in 1944.

Actual domestic consumption of bauxite in 1944 was 3,874,933 short tons (dried equivalent), a 27-percent decrease from the 5,332,151 tons consumed in 1943. Of all the domestic and foreign ore consumed, the alumina industry used 87.7 percent; chemical, 3.9 percent; abrasive and refractory, 7.5 percent; and other industries, 0.9 percent. Consumption of bauxite in the alumina industry in 1944 decreased 29 percent compared with 1943, and decreases in other industries were as follows: Chemical, 16 percent; abrasive and refractory, 17 percent; and cement, ferro-alloy, and oil refining, 13 percent. Of the bauxite consumed, 22 percent was imported, and 78 percent was domestic; 94 percent of the imported ore was used by the alumina industry.

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Primary aluminum production in 1944 dropped 15.6 percent and totaled 776,446 short tons compared with the peak of 920,179 tons reached in 1943. The annual rate of output decreased from 1,017,000 tons in January to 560,000 in December 1944 owing to curtailed operations at many of the aluminum reduction plants. Military reverses in Europe in December caused a revision of requirements, and a shortage of aluminum during 1945 was threatened. Accordingly, production of the metal was increased early in 1945. The average value of the primary aluminum shipped in 1944 was 14.32 cents a pound compared with 14.42 cents in 1943. Imports of crude and semicrude aluminum decreased 24 percent and totaled 102,753 tons in 1944; exports, on the other hand, increased 60 percent to a record high mark of 188,521 tons. Recovery of secondary aluminum totaled 325,645 tons in 1944. Apparent consumption of primary aluminum in 1944 decreased 15 percent and totaled 745,998 short tons compared with 877,381 tons in 1943.

World production of bauxite and aluminum in 1944 decreased 48 and 12 percent, respectively. The United Nations output was estimated at 72 percent of the world total for bauxite and 71 percent of the total for aluminum.

BAUXITE PRODUCTION

Domestic mine production of crude ore in 1944 dropped sharply to 3,721,135 short tons (3,162,571 tons, dried equivalent), a decline of 54 percent from the record total of 8,156,551 tons (6,980,829 tons, dried equivalent) produced in 1943. The outstanding reason for this decrease was the cancellation and termination of many of the bauxite-mining contracts between Metals Reserve Company and numerous operators. The Company cancellation-termination policy was the result of three factors: (1) A substantial drop in domestic consumption resulting from cut-backs in alumina and aluminum production ordered by the War Production Board; (2) the accumulation of excessively large stock piles, held by both Government and private industry; and (3) the assurance that the Canadian aluminum industry would be able to import its requirements from South America and not have to draw on United States stocks. The annual rate of

output had declined to about 1,450,000 short tons, dried equivalent, by December 1944.

Production of bauxite dropped 55 percent in Arkansas, 33 percent in Alabama, and 23 percent in Georgia. No output was reported from Virginia during 1944. In Saline and Pulaski Counties, Ark., whence 96 percent of the 1944 production came, 22 companies were operating mines at the beginning of the year and only 6 at the end.

Alabama.—Six mining companies produced bauxite in Alabama during 1944, and a seventh company purchased ore for consumption at its drying plant. Barbour Bauxite Co., Bauxite Co. of Alabama, Floridin Co., General Ore Co., Republic Mining & Manufacturing Co., and D. M. Wilson Bauxite Co. were active in the Eufaula district in Barbour and Henry Counties during the year. The ore was sold in crude, dried, and activated form to the alumina, refractory, chemical, and oil-refining industries. Drying plants were operated by Bauxite Co. of Alabama, Chas. Lennig & Co., Inc., and Republic Mining & Manufacturing Co. The Lennig mine and drying plant were sold to the D. M. Wilson Bauxite Co. during the year, and Chas.

Lennig & Co., Inc., reports that it does not plan any further bauxite operations in Alabama.

Arkansas.—American Cyanamid & Chemical Corp. operated the Heckler, Rauch Leased, Rauch Owned, England, and Berger No. 100 mines in Pulaski County, Ark., and the Globe No. 28, Quapaw, Ozark No. 28, and Townsend mines in Saline County. The leases on the McDonald, Ozark 24, Fletcher, Cargill, and Consolidated (Gates lease) mines were allowed to expire during 1944, and the properties reverted to control of the owners. The company continued to operate its gas-fired drying plant at Berger, Pulaski County, and a similar plant at West Bauxite, Saline County. The calcining plant at West Bauxite was not operated during the year, but the company sintering plant at the same location was active throughout 1944 and supplied sintered bauxite to the abrasive industry. Consolidated Chemical Industries, Inc., shipped chemical-grade bauxite from a stock pile at the Bierman mine in Pulaski County and from a stock pile at the Alexander No. 2 mine in Saline County on which it formerly held a lease. Crouch Mining Co., Inc. (owned by General Abrasives Co.), continued to calcine abrasive-grade ore produced from its Young mine near Bauxite, Saline County. Until the property was leased late in 1944, Dixie Bauxite Co. produced bauxite from its Dixie No. 2 mine near Sweet Home, Pulaski County, for the aluminum industry. On November 21 the mine was leased to the Dulin Bauxite Co., but Dixie continued to ship aluminum-grade ore from accumulated stocks.

Dulin Bauxite Co., Inc., mined bauxite in Pulaski County for sale to the Metals Reserve Company from the Thorpe, Ratcliffe, and Brown properties and for calcining at its own plant from the Thorpe, Harley, Dixie, Ratcliffe, Penzel and Coe, and Brown mines. Leases on the Thorpe and Harley mines were surrendered to the owners during 1944. The Ratcliffe mine was operated only from September to December, and the Penzel and Coe mine, which comprises two ore bodies mined from the same shaft, was closed because of a lack of labor from October 15 to the end of the year. The calcining plant of the company at Sweet Home operated throughout the year to supply calcined bauxite to the abrasive trade. The mine and calcining plant of the Norton Co. near Bauxite, Saline County, supplied bauxite solely for the abrasive trade during 1944. Porocel Corp. continued to operate its activating plant and its plant for the impregnation of activated bauxite with anhydrous aluminum chloride at Berger, Pulaski County; the company does not operate a mine but purchases all requirements of dried bauxite from local producers.

The Ratcliffe open-pit mine of Republic Mining & Manufacturing Co. near Sweet Home, Pulaski County, produced high-grade bauxite for sale to the nearby Drury calcining plant of its affiliate, Aluminum Ore Co., which calcined the ore for sale to the abrasive industry. In Saline County the company dried and calcined bauxite at its facilities near Bauxite for sale to alumina and abrasive plants. Underground mines operated by Republic Mining & Manufacturing Co. in Saline County included the Neilson, Section 26, Bertha, and Young; open-pit mines included the Elrod, Lantz, Section 10, Canal No. 1, Section 14, African Camp, Alexander Hill, Section 15, Lone 7th, Pruden, Pruden Extension, Poodle, Section 17, Spring Hill, Section 16, Davis (includes some underground workings), Bertha Extension

sion, South Maud, East Maud, and Middle Maud. Reynolds Mining Corp. operated the Sherrill and Hoekstra open-cut mines in Pulaski County. In Saline County the company operated the Hurricane Nos. 1 and 3, and Covington Nos. 4 and 5 underground mines, and the Stuckey open-cut mine. The Ulmer mine in Saline County was idle throughout the year, and its ore reserves are said to be exhausted.

All of the afore-mentioned companies produced ore for sale directly to the alumina, abrasive, chemical, and other industries; in addition, several sold bauxite on contract to the Metals Reserve Company for stock-piling purposes and for use in the Government-owned Hurricane Creek alumina plant. The remainder of the companies operating in Arkansas produced bauxite solely for sale on contract to Metals Reserve Company. Aluminite Mining Corp. produced ore from the Winn open-pit mine in Pulaski County from June through November when the property was closed. The McGuire and Willie Thomas open-cut mines in Pulaski County and the Ramsey open pit in Saline County were operated during January and February by the Arkansas Bauxite Stripping Co. No production is expected during 1945. Fourche Mountain Mining Co. mined bauxite from the Rauch North 20 open pit in Pulaski County in January only and probably will not operate in 1945. Hull-Macke Bauxite Mining Co. operated an underground mine on the Childress property in Saline County throughout the year. The name of the company was changed to Macke Mining Co. on June 21, 1944. Hurricane Creek Mining Co. mined from the Ozark No. 24 open pit in Saline County under a sublease from American Cyanamid & Chemical Corp. The sublease was surrendered and the corporation contract with Metals Reserve Company canceled on October 10, 1944.

The open pit on the Hoekstra-Dobbs-Illing tract in Pulaski County was operated throughout 1944 by Jackson & Squire. Kenark Mining Co. mined from an open pit on the Westminster Church-Thomas-Barner-Porter property in Pulaski County during January, and its contract with Metals Reserve Company was canceled June 5, 1944. No further operations are planned by this company. E. G. Schoffner, receiver, mined from the Sam. J. Lewis lease on the W. C. Dollar property in Pulaski County until February 1944, when the receivership was transferred to Verne McMillen. The latter operated the open-cut mine until November 15, when the Metals Reserve Company contract was canceled; no production is expected in 1945. The Gray open-cut mine in Saline County was operated by Midwest Mines Co. from January to September 1944, at which time production ceased, and the mine was reported to be exhausted. Osage Bauxite Co. mined ore from its Bryant underground mine in Saline County from January through October. The Burke-Nelson mine and the Ratcliffe Pit, both open-cut operations of the Pulaski Mining Co. in Pulaski County, were in production from January through November, but it is reported that reserves on both properties are exhausted. The underground Martin mine of Schafer & Haire Bauxite Co. near Bryant, Saline County, operated throughout 1944. Sweet Home Bauxite Co. produced ore in February only and reported that its open-cut Sweet Home mine in Pulaski County was exhausted and abandoned. Metals Reserve Company canceled its contract with Taff, Fleming, Dryden, & McWorkman on November 15, 1944; its underground Rowland mine reverted to R. M. T aylor, owner of this

Saline County property. The lease on the Wright underground mine in Pulaski County held by Wells Mining Co. was relinquished in June after suspension of mining, and no further operations are expected. The following companies which had mined bauxite in 1943 did not operate during 1944, and further operations are unlikely: Billy Bridewell and Maner Graham (Hogue-Fletcher, open pit), Clarke Bauxite Co. (Dixie lease, open pit), S. E. Evans Construction Co. (Bizzell, open pit), Leydig & Fleming (Fletcher-Hudspeth-Harris, open pit), Porter Dewitt Construction Co. (Missouri-Pacific lease), Roy Prewitt (Keenzel and Morgan open pits), and Victory Bauxite Co. (Weiss, open pit). Inasmuch as 1945 mine production is expected to be well below the 1944 total, it is very unlikely that any new operators will enter the field.

Georgia.—In Georgia both American Cyanamid & Chemical Corp. and Republic Mining & Manufacturing Co. operated mines and drying plants during 1944. Cyanamid produced bauxite from the Thig Pen mine in the Andersonville district, Sumter County, and Republic worked its mines in the Hermitage area of Floyd County. All ore was shipped to the alumina and chemical industries in dried form. No other producers were active in Georgia in 1944.

Virginia.—Some crude bauxite was shipped from stock to the refractory trade from Republic Mining & Manufacturing Co. mines near Spottswood, Augusta County, Va., but no mine production was reported during the year.

Work of Geological Survey and Bureau of Mines.—During 1944 the Geological Survey continued its work in the Arkansas bauxite area examining deposits, locating and logging drill holes, and furnishing information for war mineral reports on bauxite prepared by the Bureau of Mines. A final report on the Survey's work on bauxite is in preparation, and detailed maps showing the results of drilling are being prepared for both the Saline and Pulaski County districts. A small amount of geologic work was also done in Alabama during the year.

The Bureau of Mines continued its drilling operations in both Saline and Pulaski Counties, Ark., although the program was curtailed somewhat in 1944. In the latter part of 1943, 20 drill rigs were operating, but by the end of 1944 the number was reduced to 12. In general the objective of the drilling program during the year was to define limits of the areas favorable for the occurrence of bauxite, to explore for bauxite within those areas, and to investigate by drilling the deposits thus discovered. From the beginning of the drilling program to the end of 1944, 38 bauxite and 8 clay deposits have been discovered and either completely or partly delimited. The total number of holes drilled and accepted for payment during 1944 was 2,412, representing a total footage of 632,542. Over 16,000,000 long wet tons of merchantable bauxite in place were delimited during the year, in addition to about 26,500,000 tons of submarginal bauxite and bauxitic clay. The average tonnage of merchantable bauxite discovered per drill hole was 6,706, or 25.6 tons per foot drilled, and the average total tonnage of bauxite and bauxitic clay discovered per hole was 17,671 and per foot drilled was 67.4. From December 1941

to December 31, 1944, the total merchantable ore discovered was about 23,500,000 tons, and the total submarginal bauxite and bauxitic clay was over 34,000,000 tons. For the entire 3-year period the average discovery cost per ton of merchantable bauxite was \$0.0810, and per ton of bauxite and bauxitic clay \$0.0328 including geophysical exploration, drilling, and laboratory costs.

Bureau of Mines laboratory work on the beneficiation of low-grade bauxites to produce a Bayer-grade product continued at Rolla, Mo., and a 50-ton-a-day pilot plant for beneficiating bauxite was constructed during 1944 at Hurricane Creek, Ark., by the Bureau of Mines. Laboratory and pilot plant work on the lime-soda-sinter and various acid processes for producing alumina from clay was continued during the year by the Bureau of Mines.

Stocks.—Stocks of bauxite on hand at mines and processing plants on December 31, 1944, totaled 528,700 short tons (dried equivalent) compared with 542,100 (revised figure) on December 31, 1943. Stocks at consumers' plants decreased from 1,706,113 tons at the beginning of the year to 835,530 at the end.

CONSUMPTION

Actual domestic consumption of bauxite (as determined by special monthly consumer surveys conducted by the Bureau of Mines totaled 3,874,933 short tons (dried equivalent) in 1944 compared with 5,332,151 tons in 1943, a decline of 27 percent. The consumption figures for both years include calcined bauxite shipped for export to American-owned abrasive plants in Canada for the manufacture of crude abrasives which are returned to the United States for final manufacture and consumption. Of the 3,874,933 tons of bauxite consumed in 1944, the alumina industry used 87.7 percent or 3,397,971 tons, chemical industry 3.9 percent or 150,274 tons, abrasive and refractory industries 7.5 percent or 292,052 tons, and the cement, oil-refining, and steel and ferro-alloy industries 0.9 percent or 34,636 tons. Consumption of bauxite "as shipped" totaled 3,977,474 tons and consisted of 1,661,649 tons of crude bauxite, 2,124,276 tons of dried ore, 177,013 tons of calcined and sintered ore, and 14,536 tons of activated ore. Of the bauxite consumed (dried equivalent basis), 22 percent was foreign and 78 percent domestic. Of the foreign ore consumed the alumina industry used 94 percent and chemical, abrasive, cement, and other industries took the remaining 6 percent.

Domestic consumption, shown in the following table, is presented upon two different bases. Apparent consumption within the United States does not correspond with the data above, inasmuch as calculations are based upon shipments to domestic plants and do not consider fluctuations in consumers' stocks (including Government stock piles). Actual consumption, including shipments to Canada for processing, is based upon monthly consumer surveys and eliminates shipments destined for stock piles.

FIGURE 1.—Trends in domestic production, imports, exports, and world production of bauxite, 1915-44

Shipments, imports, exports, and apparent consumption of bauxite in the United States, 1940-44, in short tons

[Dried-bauxite equivalent]

Year	Domestic shipments from mines and processing plants to industry			Imports	Exports	Apparent consumption within United States	Apparent consumption, including shipments to Canada for processing ¹
	Arkansas	Alabama, Georgia, and Virginia ²	Total				
1940.....	490, 107	12, 995	503, 102	705, 098	134, 462	1, 073, 738	1, 200, 600

¹ Includes crude, dried, calcined, activated, and sintered.

² Includes 672,000 tons (584,640 dried equivalent) shipped to Metals Reserve Company stock piles.

³ Includes 3,791,059 tons (3,195,106 dried equivalent) shipped to Metals Reserve Company stock piles.

⁴ Includes 1,785,826 tons (1,492,594 dried equivalent) shipped to Metals Reserve Company stockpiles.

⁵ Small quantity of bauxite shipped to makers of refractories probably included under "Abrasive."

Alumina.—Bauxite consumption by the alumina industry in 1944 decreased approximately 29 percent from that in the previous year, totaling 3,397,971 tons compared with 4,761,049 tons in 1943. Of all the bauxite consumed in 1944, the alumina industry used 87.7 percent compared with 89.0 percent the preceding year. Domestic bauxite consumed totaled 2,574,681 tons or 76 percent, whereas foreign ore consumed totaled 823,290 tons or 24 percent. The industry employed crude and dried ore from Alabama, Arkansas, Georgia, Surinam, and British Guiana. Not all bauxite consumed in the manufacture of alumina is destined to emerge finally as aluminum metal, since some of the alumina is used by the chemical, abrasive, and refractory industries, and some of it is processed into special products such as activated and tabular aluminas for use in the oil-refining and ceramic

industries. Consumption of bauxite in the alumina industry is expected to decrease further in 1945.

Chemical.—The chemical industry used 3.9 percent of all domestic and foreign bauxite consumed in 1944, but consumption in the industry dropped 16 percent, exclusive of ore used to produce alumina for chemical purposes. Shipments of domestic bauxite from mines and processing plants to the chemical industry decreased 47 percent from 1943. Consumption by the industry totaled 150,274 short tons, but this included ore used to make some aluminum chemicals other than those shown in the following table and did not include a large portion of the bauxite used in the manufacture of the alumina shown in the table. Ore used to manufacture the aluminum salts and alumina shown in the table totaled approximately 309,979 tons, of which 292,935 tons (94.5 percent) was domestic, and 17,044 tons (5.5 percent) was foreign bauxite. In addition to bauxite, producers of aluminum salts reported consuming 11,279 tons of commercial aluminum trihydrate, 9,784 tons of secondary aluminum, scrap, and dross, 113,575 tons of clay, 274 tons of alunite, and a quantity of bichromate residue.

Production and shipments of aluminum salts increased 3 percent in quantity and value in 1944. Production of alumina (aside from that used in making aluminum) decreased 10 percent, and shipments decreased 11 percent. Of this alumina, only 9 percent was consumed by aluminum salts producers; the remainder was used by manufacturers of abrasives, refractories, petroleum products, spark plugs, glass, rubber, paints, and various other commodities.

Aluminum salts and alumina produced and shipped in the United States, 1943-44

¹ 147 pounds in 1941 and 50 pounds in 1942.² Revised figure. Salts made from iron-free aluminum sulfate omitted.

Abrasive and refractory.—Manufacturers of crude aluminous abrasive pigs in Canada and the United States and manufacturers of bauxite refractories in the United States used 292,052 tons (7.5 percent) of all the foreign and domestic bauxite consumed in 1944, a 17-percent decrease from the 352,423 tons used in 1943. Except for a relatively small quantity from British Guiana, all the ore requirements of the industry were supplied from Saline and Pulaski Counties, Ark.

Other.—Consumption of bauxite in the cement, steel, ferro-alloy, and oil-refining industries decreased 13 percent in 1944. However, the use of thermally activated bauxite as a drying adsorbent² and as a catalyst and catalyst carrier³ has become increasingly important during the past year.

*Principal bauxite consumers in the United States during 1944***Abrasive and refractory industries:**

Abrasive Co., Philadelphia, Pa.
 Babcock & Wilcox, Old Savannah Road, Augusta, Ga.
 The Carborundum Co., Niagara Falls, N. Y.
 Corhart Refractories Co., Sixteenth and Lee Streets, Louisville 10, Ky.
 The Exolon Co., Tonawanda, N. Y.
 General Abrasive Co., Inc., Niagara Falls, N. Y.
 Monsanto Chemical Co., 1700 South Second Street, St. Louis, Mo.
 Norton Co., 50 New Bond Street, Worcester 6, Mass.

Alumina industry:

Chemical industry—Continued.

Gulf Oil Corp., Post Office Box 1166, Pittsburgh 30, Pa.
 Hercules Powder Co., 908 Market Street, Wilmington, Del.
 Hilton-Davis Chemical Co., Post Office Box 8, Pleasant Ridge Station, Cincinnati 12, Ohio.
 Charles Lennig & Co., Inc., 222 West Washington Square, Philadelphia 5, Pa.
 Monsanto Chemical Co., 1700 South 2d St., St. Louis, Mo.
 Pennsylvania Salt Mfg. Co., Widener Building, 1335 Chestnut Street, Philadelphia 7, Pa.
 Stauffer Chemical Co., 624 California Street, San Francisco 8, Calif.
 Westvaco Chlorine Products, Carteret, N. J.

Municipal water works:

Birmingham Water Works Co., 50 Broad Street, New York 4, N. Y.
 Board of Public Utilities, Kansas City Water Department, Kansas City 16, Kans.
 Bureau of Water Supply, Baltimore 12, Md.
 City of Columbus Purification Works, Columbus 8, Ohio.
 Kansas City Water Department, Kansas City 6, Mo.
 Metropolitan Utilities District, Water Department, Eighteenth and Harney Streets, Omaha 2, Nebr.
 Passaic Valley Water Commission, Box 268, Little Falls, N. J.
 City of Sacramento, Filtration Division, Sacramento 16, Calif.
 United States Engineer Office, Dalecarlia Filter Plant, Washington, D. C.

Other industries:

Atlas Lumnite Cement Co., Chrysler Building, New York 17, N. Y.
 Crucible Steel Co. of America, 405 Lexington Avenue, New York 17, N. Y.
 Electro Metallurgical Company, 30 E. Forty-second Street, New York 17, N. Y.
 Vanadium Corporation of America, 420 Lexington Avenue, New York 17, N. Y.

This list does not include many oil-refining companies which are small users of activated bauxite.

PRICES

In 1944 the average selling price, f. o. b. mines and processing plants, was \$3.87 per short ton for crude (undried) bauxite, \$4.99 for crushed dried bauxite, \$12.65 for calcined bauxite, and \$50.60 for activated bauxite. Values per long ton were as follows: \$4.33 for crude, \$5.59 for dried, \$14.17 for calcined, and \$56.67 for activated. The average value for all grades of domestic ores as shipped was \$4.85 a short ton (\$4.56 in 1943) or \$5.43 a long ton (\$5.11 in 1943). Nominal market quotations, given in the following table from E&MJ Metal and Mineral Markets, remained static in 1944 for all grades of domestic bauxite.

The Metals Reserve Company purchased bauxite in Arkansas throughout 1944 for delivery to the stock-pile depots at Sweet Home, Ward Spur, and Hurricane Creek. The special price schedule (next page) set up by Metals Reserve Company is based on percentages of contained alumina, silica, and ferrous iron. The base price is \$4.15 a long ton for ore containing 50 percent Al_2O_3 , 13 percent SiO_2 , and less than 6 percent FeO . Bonuses are as follows: 20 cents a ton for each percent of silica under 13, and 14 cents a ton for each percent of alumina over 50. Penalties are as follows: 43 cents a ton for each percent of silica over 13; 14 cents for each percent of alumina under 50; and 43 cents for each percent of iron in the ferrous state calculated as FeO . This price schedule has been in effect since September 1943.

FOREIGN TRADE

Imports of bauxite in 1944 decreased 64 percent from 1943, dropping to 627,716 short tons, the lowest since 1939. Exports decreased 65

percent and totaled 164,234 tons as shipped, dropping almost to the 1941 level. Of the 1944 imports, 580,393 tons came from Surinam, 47,323 tons from British Guiana, and less than 1 ton from Canada, according to the United States Department of Commerce. By customs districts, imports were as follows: 610,114 tons at Mobile, 5,827 tons at New York, 4,134 tons at Philadelphia, 3,839 tons at Massachusetts, 3,802 tons at New Orleans, and less than 1 ton at St. Lawrence.

² Chiefly dried ore.

³ As shipped.

Of the 1944 exports, 147,900 short tons were classified as bauxite and other aluminum ores and 16,334 tons as bauxite concentrates (including alumina). Canada was the largest recipient of the exports, 146,862 tons of bauxite and other aluminum ores being shipped to that country; only 643 tons went to Iran, 394 tons to Curaçao, and 1 ton or less each to Egypt, Algeria, and the United Kingdom. Aside from shipments to Canada, the exports consisted almost entirely of activated bauxite destined for use in oil refineries. Bauxite concentrates (including alumina) were exported to the following countries: Canada 15,866 tons, Trinidad and Tobago 243 tons, Iran 184 tons, Curaçao 40 tons, and U. S. S. R., Brazil, and Mexico each 1 ton or less.

ALUMINUM**PRODUCTION**

Primary.—The production of 776,446 short tons of aluminum metal in 1944—15.6 percent below the all-time record of 920,179 tons set in 1943—resulted in a reverse in a production curve which had climbed steadily for the previous 5 years. The decline in output was due to several cut-backs in plant operation ordered by the War Production Board during 1944, owing to growing stocks of metal and reduced military requirements. Late in the year, however, revisions in military requirements brought about by December reverses on the western front threatened to create a shortage of aluminum in 1945. Early in 1945, accordingly, production was ordered raised 5,000 tons a month by the War Production Board. Total output in 1945 is expected to be at least 10 to 15 percent below that in 1944. In January 1944 the annual rate of aluminum production was 1,017,000 tons, but by December it had fallen to about 560,000 tons.

By far the largest share of the 1944 output was supplied by the five aluminum-reduction plants owned by the Aluminum Co. of America (Alcoa) and the eight plants owned by the Defense Plant Corporation and operated by Alcoa under a management contract. Reynolds Metals Co., with its two plants at Listerhill, Ala., and Longview, Wash., and Olin Corp., operator of the Defense Plant Corporation plant at Tacoma, Wash., supplied the remainder of the domestic output. Approximately 55 percent of the production was from privately owned facilities and 45 percent from Government-owned plants. Of the Alcoa output from its own plants, 40 percent was made at Alcoa, Tenn., 24 percent at Vancouver, Wash., 21 percent at

Massena, N. Y., 9 percent at Badin, N. C., and 6 percent at Niagara Falls, N. Y. Production from the Alcoa-operated Government-owned plants was distributed as follows: 29 percent at Mead (Spokane), Wash., 20 percent at Jones Mills, Ark., 16 percent at Troutdale, Oreg., 13 percent at Queens, N. Y., 11 percent at Los Angeles, Calif., 7 percent at Riverbank (Modesto), Calif., 3 percent at Burlington, N. J., and 1 percent at St. Lawrence (Massena), N. Y. The Listerhill (Ala.) plant of Reynolds Metals Co. supplied 61 percent of Reynolds production, and the Longview (Wash.) plant the remaining 39 percent. The value of the primary aluminum shipped in 1944 averaged 14.32 cents a pound compared with 14.42 cents in 1943 and 14.62 cents in 1942.

Cut-backs in aluminum production ordered by the War Production Board from December 15, 1943, to August 30, 1944, totaled 608,000 ⁴ short tons of annual capacity, leaving only about 560,000 short tons, or 48 percent, of annual installed capacity in operation during the last third of the year. Of the privately owned plants, no cut-backs were ordered for the Reynolds Metals Co. operations, but Alcoa's plants were cut about 29 percent from rated capacity. Production at the Alcoa-operated Defense Plant Corporation plants was cut 75 percent, but at the Olin-operated DPC plant output was left at capacity. Three of the DPC plants are now being used for other purposes—the Queens (Long Island) plant was taken for use by the Navy Department, and the Burlington (N. J.) and Riverbank (Calif.) plants are being used as surplus-property disposal centers by Reconstruction Finance Corporation.

The 500,000-ton Defense Plant Corporation alumina plant at Baton Rouge, La., was closed in the summer of 1944, and substantial cut-backs were ordered at the DPC plant at Hurricane Creek, Ark., and the two Alcoa plants at East St. Louis, Ill., and Mobile, Ala. As a result, production of alumina dropped 63 percent from the peak month of October 1943 to November 1944. Production was increased in December 1944 and early 1945 to assure sufficient supplies of calcined alumina for the 5,000-ton-a-month increase in aluminum metal ordered by WPB early in 1945. The lime-soda-sinter units at the East St. Louis and Hurricane Creek plants went into commercial operation during 1944 to treat the red-mud residues from the Bayer process. It is planned that operation of these units will be enlarged to the point where all the treatable red mud from both plants will be used. Expected recovery of alumina from high-silica domestic bauxites (up to 12.5 percent silica) will be raised from about 70 percent by the Bayer process alone to 85 to 90 percent by the combination process.

The Kalunite, Inc., DPC plant for producing alumina from alunite at Salt Lake City, Utah, has been disappointing in results. Although the plant was substantially complete in the summer of 1943, production has been less than 5 percent of capacity. The small quantity of alumina produced has been shipped to the Olin Corp. aluminum plant at Tacoma, Wash., where test runs have been made on the material in segregated reduction pots. At Salem, Oreg., the Chemical Construction Co. had not yet completed construction for DPC of a plant to use an ammonium sulfate process on Oregon clays. The

⁴ Includes 3 potlines completed but never put into operation because of manpower shortage.

plant is expected to be completed in the fall of 1945, but whether it will operate at that time will depend on the supply situation of ammonium sulfate—now scarce because of agricultural requirements. Anorthosite will be treated in a lime-soda-sinter process to recover alumina in a plant being built for DPC by Monolith Midwest Corp. at Laramie, Wyo. The plant, expected to start operation in September 1945, will also yield a byproduct usable in the cement industry. The lime-sinter soda-leach process plant built for DPC at Harleyville, S. C., by Ancor Corp. began experimental operation in October 1944 and started commercial production of alumina from clay early in 1945.

Pursuant to legislation signed by President Roosevelt on June 10, 1944 (Public Law 332), the Government antitrust case against the Aluminum Co. of America was sent on June 12 to the Second Federal Circuit Court in New York for final action, since four Supreme Court justices had disqualified themselves in 1942. The appeal by the Government to the Supreme Court came after the New York Federal District Court held in 1941 that the Department of Justice had failed to prove its charges that the Aluminum Co. of America had violated the Sherman antitrust law. The appeal was heard by three circuit court judges, who under Public Law 332 sat as a panel of the Supreme Court, and the decision handed down on March 12, 1945, held that the district court had erred in finding that Alcoa had not operated in violation of section two of the Sherman Act. In discussing the Government contention that dissolution of Alcoa should be ordered, the court said:

It is as idle for the plaintiff to assume that dissolution will be proper as it is for Alcoa to assume that it will not be. And it would be particularly fatuous to prepare a plan now, even if we could be sure that eventually some form of dissolution would be proper. Dissolution is not a penalty but a remedy; * * * The need for such a remedy will be for the District Court in the first instance, and there is a peculiar propriety in our saying nothing to control its decision, because the appeal from any judgment it may enter will perhaps be justiciable only by the Supreme Court, if there are then six justices qualified to sit.

Thus, the question of whether Alcoa is to be dissolved eventually was left unsettled. The court recognized, however, that the situation had changed during the war years and, although Alcoa in fact monopolized the virgin ingot market as recently as 1940, it did not follow that this would be true after the war, as the Defense Plant Corporation and the Reynolds Co. held more than 50 percent of the country's aluminum-ingot capacity.

In October 1944 the Department of Justice, acting under the provisions of the Surplus Property Disposal Act, refused to approve the sale of three Defense Plant Corporation-owned aluminum plants to Alcoa on the grounds that such action would contribute to the growth of monopoly. The plants had not been technically declared surplus by the end of 1944, but when they are so declared, Alcoa will not receive consideration as a prospective purchaser.

Negotiations for a new collective bargaining contract between the Aluminum Workers of America, C. I. O., and the Aluminum Co. of America opened on January 20, 1944. The union presented its demands for a 15-cent-an-hour wage increase, a uniform hiring rate of 95 cents an hour, and a uniform wage structure in all plants (that is, elimination of the North-South wage differential) to the War Labor

Board. The union asked that these demands, or any modifications of them directed by the War Labor Board, be made retroactive to January 20 and that the Board rule on this issue before considering the merits of the wage dispute. The Board declined this last demand and stated that the issue of retroactivity would be properly taken up when the dispute was decided. Negotiations and hearings continued throughout the year, and finally on March 28, 1945, a decision was handed down by the War Labor Board including the following: The hourly base pay raise of 15 cents was denied, as was the union demand for a 95-cent-an-hour minimum hiring rate; a union demand for a guarantee of no less than 40 hours' pay for every week in the year was denied; Alcoa was directed to check off union dues up to \$1.50 a month and initiation fees of \$3.00; and the second- and third-shift differentials were raised from 3 and 5 cents to 4 and 6 cents and made retroactive to May 1, 1944.

FIGURE 2.—Trends in domestic primary and secondary production and world production of aluminum, 1915-44.

Secondary.—Recovery of secondary aluminum in 1944 totaled 325,645 short tons compared with 313,961 tons in 1943 and 196,464 tons in 1942. The 325,645 tons recovered from secondary sources included 2,336 tons of pure metal (98.5+ percent), 320,040 tons of aluminum alloys, 1,466 tons of aluminum in brass and bronze, 187 tons in zinc-base alloys, and 1,616 tons of aluminum in chemical compounds. Production in the form of secondary ingots totaled 214,879 tons (196,373 tons in 1943). The secondary aluminum

recovered in 1944 required the consumption of 354,182 tons of aluminum scrap, of which 25,223 tons (7 percent) was old scrap (34,266 tons or 10 percent in 1943) and 328,959 tons (93 percent) was new scrap (317,858 tons or 90 percent in 1943). Remelters, smelters, and refineries used 62 percent of this scrap; aluminum rolling mills, 34 percent; and foundries and other manufacturers, 14 percent. Additional information on secondary aluminum is given in the chapter on Secondary Metals—Nonferrous.

CONSUMPTION

Apparent domestic consumption of aluminum in 1944 dropped to 745,998 short tons—15 percent below that in 1943 (877,381 tons).

No statistics on aluminum consumption are available, and therefore no precise appraisal of total actual consumption or consumption by use can be made. However, data on shipments of aluminum, including both primary and secondary metal in ingot, semifabricated, and fabricated form are gathered by the War Production Board in connection with its job of regulating supply and of allocating the available supply to various claimant agencies under the Controlled Materials Plan. These data indicate that, of the shipments for domestic use, approximately 64 percent was destined for aircraft construction, 21 percent for Army and Navy use, and 15 percent for other uses including essential civilian uses.

Aluminum is used in aircraft construction mainly in air frames, landing gear, engines, propellers, and fittings. The importance of the metal to the heavy-bomber program is indicated in a statement by Alcoa to the effect that a B-29 Superfortress requires more than 50,000 pounds of aluminum, including 23,000 pounds of sheet, 18,000 pounds of extruded shapes, 550 pounds of tubing, 150 pounds of rod, bar, and wire, 750 pounds of rivets, 2,000 pounds of castings, 400 pounds of forging, and approximately 6,500 pounds in engine parts and miscellaneous applications. During 1944, 96,369 planes of all types were delivered to the armed forces, and the average total weight per plane was 10,600 pounds; it is estimated that at least 50 percent was aluminum or aluminum alloys.

Tank engines, ordnance, airplane landing mats, and ship construction consumed the bulk of the shipments for Army and Navy use. Among naval units, an aircraft carrier uses the most aluminum, requiring about 2,000,000 pounds. Next are battleships, using about 1,400,000 pounds each, followed by heavy cruisers, 600,000 pounds; light cruisers, 500,000 pounds; destroyers, 225,000 pounds; large auxiliary ships, 60,000 pounds; small auxiliary ships, 20,000 pounds; and submarines, 15,000 pounds. Airplane landing mats, weighing about one-half as much as the older steel-type mat, and aluminum gasoline drums, weighing 21 pounds each, as compared with 52 pounds for those of other materials, were new military applications of aluminum in 1944. Another interesting and important use of the metal during the year was the thin strips of aluminum foil dropped from bombers and fighter planes over enemy territory to confuse the enemy's radar-directed anti-aircraft batteries.

The remainder of the shipments of aluminum during 1944 were largely destined for indirect military and essential civilian uses.

Among the authorized uses of the metal were the following: Box and hopper railroad cars, trucks and busses, chemical equipment, steel deoxidizing, foundry equipment, foil for wrapping purposes, collapsible tubes, metal containers (including cans), aluminum paint, cooking utensils, food-processing machinery, and domestic laundry equipment. The relaxation of controls over aluminum in midyear did not result in greatly increased consumption for civilian consumer goods, largely because manpower difficulties often prevented manufacture even when metal was available. In the latter part of 1944 a number of "Z" allotments—deferred authorization contingent on the availability of aluminum—were granted by the War Production Board for civilian goods manufacture, but only a relatively few deliveries were made.

FIGURE 3.—Trends in imports, exports, and apparent consumption of aluminum, 1915-44.

¹ Data not available on fluctuations in consumers' stocks. Withdrawals from producers' stock totaled 30,188 tons in 1940 and 55,320 in 1944; additions to producers' stocks totaled 12,232 tons in 1941, 5,502 in 1942, and 60,787 in 1943.

² Based upon average price of primary aluminum as reported to Bureau of Mines.

PRICES

During 1944, as in the previous 2 years, the New York open-market base price of primary aluminum remained at 15 cents a pound for lots of 10,000 pounds or more, 99-percent-plus virgin ingot aluminum, delivered. Pig aluminum remained at 14 cents, delivered, throughout 1944 for 99-percent-plus pigs. Quoted prices for remelted pig, 97.5 percent pure, delivered, ranged from 11 cents to 12.5 cents a pound and averaged 11.733 cents for the whole year. Remelted No. 12 alloy, delivered, ranged from 9.25 to 10.5 cents a pound and averaged 10.226 cents in 1944.

FIGURE 4.—Trend in average quoted price of aluminum, 1915-44. Price is for No. 1 virgin 98-99 percent at New York through 1929. Thereafter for 99-percent-plus virgin ingot, as reported by American Metal Market.

FOREIGN TRADE

Imports of crude and semicrude aluminum in 1944 decreased 24 percent in tonnage and 27 percent in value from those in 1943 and amounted to 102,753 tons valued at \$30,229,982. On the other hand, exports of crude and semicrude aluminum increased 60 percent in quantity and 25 percent in value over 1943, reaching an all-time high mark of 188,521 tons valued at \$73,578,734. The value of exports of manufactured aluminum products increased 106 percent, whereas the value of imports decreased 82 percent in 1944. Imports of aluminum (crude metal and alloys only) constituted 13 percent of the ap-

TECHNOLOGIC DEVELOPMENTS

The Alcoa combination process for the recovery of alumina from high-silica bauxite was used successfully during 1944 at the Hurricane Creek and East St. Louis alumina plants. By re-treating red-mud residues from high-silica bauxite a recovery of 85 to 90 or more percent of the total alumina contained in the ore is obtained, whereas the same ore treated only by the Bayer process would show a recovery of about 70 percent. A new alumina development laboratory⁵ of Aluminum Research Laboratories at the East St. Louis (Ill.) works of the Aluminum Ore Co., which was designed and built at a cost of \$750,000.

⁵ Chemical Industries, Alcoa's New Aluminum Development Laboratory, January 1945, pp. 54-58.
 Edwards, J. D., The Combination Process for Alumina: Metals Technol., vol. 12, No. 3, Tech. Pub. 1833, April 1945, 6 pp.

was completed in 1944. The newly completed laboratory includes pilot-plant facilities for the development of improved operating technique, economy in use of materials, and improved quality of product in the Alcoa combination process. Aluminum Research Laboratories has been working on methods of recovering alumina from low-grade aluminous materials for a number of years and had developed the lime-soda-sinter process for recovering both alumina and caustic from Bayer-plant waste. Because of the urgency for maximum production of alumina—for which a large proportion of domestic bauxite had to be used—it was necessary to build the pilot plant and the four commercial units⁶ concurrently.

As commercial operation at the large sinter units now being used does not permit adequate experimental work necessary to develop the process to its full value, the data and experience to be obtained from the pilot plant will have great value. The laboratory is equipped with a complete Bayer unit on a small scale which can be operated separately or in combination with various waste-recovery processes.

In the combination process Bayer-process waste or red mud is sintered with a slight excess of limestone and soda ash over that necessary to combine with the silica and alumina, then leached with a caustic soda solution to give a solution of sodium aluminate and caustic soda which is returned to the digester circuit. The process is said to be so effective when used with the Bayer process on high-silica ores that the proportion of alumina recovered from bauxite containing 10 to 15 percent silica is as high or higher and the soda loss lower than in the Bayer process alone operating on high-grade bauxite. The combination process appears to open up the possibility that domestic low-grade bauxite may be as economical as imported bauxite when the inland plants at Hurricane Creek and East St. Louis are considered. The lime-soda-sinter process is definitely to be classed as one of the major technologic advances of the past decade in the aluminum industry.

Military demand for bombers of longer range and greater load-carrying capacity and for higher-performance combat planes has stimulated the search for stronger aluminum alloys. Alcoa alloy X76S, a heat-treatable alloy with magnesium and zinc as the principal alloying ingredients, was announced in 1944, though it had been in use for forged-aluminum propellers for 3 or 4 years.⁷ During 1944 another alloy, 75S was put into commercial production in the form of extrusions and aluminum-clad sheet. Magnesium, zinc and copper are the main alloying ingredients. Extrusions have a tensile strength of 80,000 p. s. i. (pounds per square inch) and a yield strength of 88,000 p. s. i., or about 50 percent above the best high-strength aluminum alloys formerly obtainable. A new Reynolds alloy, R-303, is an aluminum-magnesium-zinc alloy with high tensile and yield strength. Other important developments have been the introduction of two alloy-clad sheet alloys, R-301 and 14S. All five alloys are finding important applications in the manufacture of military aircraft.

⁶ At Baton Rouge, La.; Mobile, Ala.; Hurricane Creek, Ark.; and East St. Louis, Ill.

WAR MEASURES

War Production Board Conservation Order M-1-i, which governed all uses of aluminum other than scrap, and paint and pigment, was amended March 24 and July 15, 1944, to relax its restrictions somewhat and finally was revoked on August 15, 1944. On the same date the Board's Limitation Order M-1-k was issued, specifically removing restrictions on all the uses of aluminum, exclusive of those provided for in regulations under the Controlled Materials Plan, and Orders M-1-d (scrap) and M-1-g (aluminum, paint and pigment), except that household and kitchenware might be made only as described in Order L-30-e, and restrictions established by other War Production Board orders as to quantity, size, and type of articles manufactured would remain. In spite of this apparent concession to the manufacturers of civilian goods from aluminum, Priorities Regulation 25, also issued August 15, stated that civilian production could proceed only where manpower and facilities were available and not needed for essential war purposes. As a result, production of civilian consumer goods late in 1944 was not greatly increased by the revocation of Order M-1-i, but its effects probably will be felt in an increase in the manufacture of aluminum goods for civilians during 1945.

Order M-1-d, covering scrap aluminum, as amended September 22, 1944, provides only that all persons dealing in scrap shall keep records and make reports to the War Production Board and that special directions may be issued by the Board relative to use, receipts, delivery, and segregation of scrap.

Order M-1-g, relating to aluminum paint and pigment, as amended September 11, 1944, requires only that persons seeking to obtain aluminum pigment shall apply to the War Production Board and that no producers shall deliver it except on orders authorized by the Board, except under Order P-43 (research, developmental, or experimental purposes).

The distribution of aluminum during 1944 continued to be governed by the Controlled Materials Plan, by which production programs of claimant agencies are adjusted to conform with available supply and allotments are granted to claimant agencies in the quantity and forms necessary to meet authorized programs and schedules.

On October 23, 1944, General Preference Order M-1-h allocating bauxite and alumina was revoked. These commodities are now free of restriction as to use, since the available supply exceeds requirements.

POSTWAR OUTLOOK

Present productive capacity in the aluminum industry, expanded some seven times since 1939, has proved large enough to satisfy all military and essential civilian needs during the war period, even without full operation at any time. By the end of 1944 all needs were being filled, with output at only about half of total rated annual capacity. The realization that even full wartime demand has not required the use of all aluminum-producing facilities has stimulated considerable thought about the prospects of the industry during the postwar years. Unlike most other metals, aluminum has been lowered 25 percent in price during the war period and is now sold for

15 cents a pound in ingot form. Available data indicate that all of the privately owned production facilities in the country—about half of the total—can produce the metal at a profit at its present price and that perhaps 50 percent of the Government-owned capacity can meet the present price. The postwar period may bring further reductions in price, although this is by no means assured. One certainty is that, with respect to cost, aluminum has been considerably improved in relation to other metals during the war and that much if not all of this relative gain can be held. Among the major industrial metals aluminum appears to have established itself in a strong position for greatly enlarged use in the postwar years, compared with the prewar period.

The disposition of the large stocks of metal in ingot, semifabricated, and fabricated form, which are likely to be on hand at the end of hostilities, is an important factor to be considered in evaluating postwar production of new aluminum. Stocks on hand, including metal in process at aircraft plants and other consumers, metal in the hands of scrap dealers, metal in plant inventories and in process in the aluminum industry, and Government stock piles, were estimated to total over 1,000,000 tons early in 1945. Dumping any substantial part of this metal on the market would cause serious hardship to the aluminum-production industry. It is possible that if prompt action is taken under section 22 of the Surplus Property Act of 1944 (Public Law 457—78th Cong.) a large share of this quantity could be held in a strategic stock pile as a protection against any future emergency. However, the freezing provisions of this bill expire January 2, 1946, and unless Congress extends the provisions of this section of the act or enacts other stock-pile legislation, the postwar surpluses of aluminum will weigh heavily on postwar markets.

Consumption of aluminum and aluminum products in the immediate postwar years probably will be relatively large in those industries that will have a pent-up demand accumulated during the war such as that for cooking utensils and other small consumer items, although total consumption is expected to drop sharply from the war period because airplane construction and other wartime uses will experience an abrupt decline. After the immediate readjustment period, consumption of aluminum will increase in the larger heavy industries, including building construction, railroad rolling stock, and truck, bus, and possibly automobile manufacture. Resumption of civilian plane construction, both private and commercial, will also require aluminum, but it is not likely that this use will be a major factor in the aluminum industry for several years. A steady demand for a moderate number of military aircraft, if national policy should demand maintenance of a powerful air force, would be a major outlet.

Estimates of consumption of primary aluminum by the fourth or fifth year after the war have varied widely and range from 250,000 to more than 700,000 tons, assuming a price of 15 cents a pound. At lower prices, of course, use of aluminum would rise in products where its competitive position with other materials is very close. In certain industries, such as bus, railroad equipment, and aircraft manufacture, where light weight is a controlling factor, small price changes would have little effect on total use, since long-term operating costs are more important than first cost. In other industries, however, where first cost is a more important factor, such as the automobile, cooking

utensil, washing machine, electrical appliance, and building construction, the consumption of aluminum would be greatly affected by fluctuations in price.

Bauxite, the raw material from which virtually all aluminum is produced, is found in abundant quantities throughout much of the world, but domestic reserves of high grade are very limited. Lower grade bauxites, for which extraction processes have been developed during the war, occur more abundantly in the United States but still represent a limited resource. It seems likely that a large share of the bauxite consumed to make aluminum after the war will be imported from South American and Caribbean areas, where reserves are very large. If these sources of supplies should be cut off for any reason, domestic bauxites and possibly clays could supply domestic needs in an emergency. Such reliance on domestic higher-cost resources might be reflected in the price of aluminum, but its effect on the final cost of finished products made from the metal would be very slight.

The United States will continue to occupy an important position in the world aluminum industry after the war. Although it is doubtful if the domestic industry can compete favorably in the world market for ingot metal with many foreign producing countries, particularly Canada, it seems relatively certain that with American mass-production techniques and low unit cost of fabricated products, articles made from aluminum, such as cooking utensils and other items, can compete to advantage in many foreign markets.

WORLD BAUXITE AND ALUMINUM INDUSTRIES

World production of bauxite and aluminum in 1944 decreased greatly from 1943, partly because of overproduction and decreased demand in certain of the United Nations and partly because of bombings, transportation disruptions, and invasions in certain of the Axis countries. Output during 1945 is expected to be somewhat less than in 1944.

World production of bauxite is estimated to have totaled 6,953,000 metric tons in 1944—a drop of 48 percent from the all-time record of 13,247,300 (estimated) in 1943 and only slightly above the production in 1941. The bulk of the decrease is accounted for by a large drop in production in the Western Hemisphere—approximately 5,500,000 tons—owing to cut-backs in metal production in the United States and Canada and to large stock piles of ore in the United States. Of the world output in 1944, it is estimated that 1,936,700 tons (28 percent) were produced in Axis-controlled areas, whereas 5,014,200 tons (72 percent) were produced in areas under control of the United Nations. The balance of 2,500 tons was produced in neutral areas.

The 12-percent decrease in the estimated world production of aluminum in 1944 is largely accounted for by cut-backs in Canada, United States, and the United Kingdom. Some decrease was noted among the Axis-controlled areas—notably France and Italy—as a result of air bombardment and reconquest by the Allies. It is estimated that approximately 505,000 metric tons or 29 percent of the total aluminum was produced in Axis-controlled areas, 1,230,976 tons or 70.6 percent in areas of United Nations control, and 7,706 tons or 0.4 percent in neutral countries.

REVIEW BY COUNTRIES

Brazil.—After prolonged delays owing to difficulties in obtaining equipment and in solving technical problems, the Companhia Electro-Chimica Brasileira finally began production at its alumina and aluminum plants near Ouro Preto, Minas Gerais, in April 1945. This is

the only one of several aluminum projects in Brazil that has proceeded beyond the planning stage. Capacity of the metal plant has been variously estimated at 2,000 to 2,500 tons annually, and capacity figures for the alumina plant have ranged from 6,000 to 10,000 tons annually. The bauxite used at the alumina plant is obtained from nearby deposits and is said to contain about 54 percent Al_2O_3 and to have a low silica content. Power from a hydroelectric plant located a few kilometers away is said to be supplied at a cost of 3 to 3.5 mills per kilowatt-hour, allowing for amortization of the facilities over a 30-year period. The anticipated annual production of 2,000 to 2,500 tons will be sufficient to satisfy Brazil's domestic needs if they are near the prewar level. The quantity of bauxite produced during 1944 is not known but probably was about 5,000 tons. Exports totaled 2,979 tons, of which 1,250 tons were shipped to Argentina for alum manufacture, 1,699 tons were sent to the United Kingdom, and 30 tons were destined to Chile.

British Guiana.—Exports of bauxite in 1944 dropped to about 40 percent of the 1943 total and averaged less than 78,000 tons a month. The decline in both production and exports was due to decreased demands from Canada and the United States and to reduced shipping quotas necessitated by a shortage of bottoms. Since bauxite mining is the most important industry in the colony, the large decrease in output affected revenues greatly. The Demarara Bauxite Co., with its mines at Mackenzie City, was the only company operating during 1944, since the Berbice Bauxite Co., Ltd. (a subsidiary of American Cyanamid & Chemical Corp.), had ceased mining at its properties late in 1943.

Canada.—Owing to curtailed war demands and decreased export requirements for Great Britain and the United States, production of ingot aluminum in the province of Quebec, Canada, in 1944 declined about 7 percent from the record high mark reached in 1943. Late in November 1944 the Aluminum Co. of Canada announced that it would curtail production about one-half by December 10. It was announced that about 2,500 workers would be laid off as a result of the cut-back. Officials of the company stated, however, that they did not expect production of metal to fall to the prewar level, even temporarily. The export sales organization of the company is actively rebuilding to establish new peacetime foreign outlets. Undoubtedly, the United Kingdom will continue to be a good customer for Canadian metal, but the large wartime exports to the United States will not continue after the war.

China.—According to a recent report,^a the first bar of primary aluminum produced in Free China was displayed at the Chinese Government Industrial and Mining Exhibition in 1944. The metal was produced in December 1943 in an experimental plant in Yunnan Province, which has a capacity of about 1 ton a day. It is reported that negotiations for the construction of two reduction plants are taking place.

Dominican Republic.—According to reliable sources, geologists of the Republic Mining & Manufacturing Co. have been conducting exploratory work for bauxite deposits in the central part of Barahona Province. The Reynolds Metals Co. is understood to have aban-

^a Chang, T. Y., *China's Cinderella Industry*: Min. Jour. (London), vol. 222, No. 5686, Aug. 12, 1944, p. 490.

doned its work in the country. On May 3, 1944, the National Congress of the Dominican Republic passed Law 575, specifying conditions under which contracts may be made between the Government and private individuals or companies for exploration and exploitation of lands containing bauxite and other aluminous materials. This law stated that a tax of 10 cents per hectare annually and a royalty of 10 cents per ton of ore extracted would be levied by the Government and that contracts would be valid for not more than 30 years but would be renewable.

France.—Reliable data concerning the French bauxite and aluminum industries during the period of German occupation show that bauxite production was considerably lower in 1940 and 1941 than had been previously believed, whereas the estimated metal output during these years was very close to the actual figures. A sharp rise in bauxite production in 1943 reflects the efforts of the Nazi Todt Organization to stimulate output after the occupation of southern France in November 1942. The production rate was increased again during early 1944, but the output fell to about the 1942 level for the whole year, inasmuch as mining had virtually ceased after August 15. Domestic consumption of bauxite, as indicated by shipments from mines to French industry, was virtually constant at 420,000 to 450,000 tons annually from 1940 through 1943. Shipments declined sharply in 1944 owing to the drop in mine output and to the paralysis of transport facilities in the latter third of the year. Deliveries of bauxite to Germany rose from none in 1940 to about 230,000 tons in 1941 and 1942. After the occupation of southern France, deliveries were greatly accelerated and totaled about 480,000 tons in 1943 but dropped to less than 300,000 tons in 1944.

Efforts by the Nazis to stimulate production of aluminum were not as effective as for bauxite. French aluminum output reached a record high of about 64,000 tons in 1941 but declined about 25 percent in 1942 and 1943. Production in 1944 totaled less than half the 1940 output owing to virtual cessation of operation in August.

On January 1, 1945, bauxite stocks in France totaled about 350,000 tons, which is thought to be adequate for domestic requirements in 1945. Before the war domestic consumption of French bauxite was distributed as follows: 91.5 percent for aluminum, 3.8 percent, for abrasives, 2 percent for refractories, 1.5 percent for cement, and 1.2 percent for other uses. Only two French bauxite mines, representing about 3 percent of the total output, were damaged during the war—the Saint-Christophe mine at Vins in the Var and the Rouenmale mine in Hérault.

It is believed that damage to alumina and aluminum plants during the war was relatively slight and that necessary repairs have already been nearly completed. Production of aluminum during 1945 depends largely on the speed with which transport can be reorganized and on the availability of coal.

Germany.—German and Austrian aluminum production in 1944 is estimated at about 300,000 metric tons. Although annual capacity of plants in the two countries was probably 350,000 to 400,000 tons in 1944, it is extremely doubtful if the industry was able to approach capacity output in the face of Allied air raids. Transportation and power difficulties must have been almost insurmountable during the nearly continuous bombing raids, and the labor situation

was undoubtedly difficult. With the loss during 1944 of France and part of the Yugoslav Adriatic coast, Germany was cut off from two important bauxite sources.

Gold Coast.—The bauxite boom in Gold Coast, which reached its peak during 1943, appears to be definitely on the wane, and 1944 production dropped 33 percent from that of the previous year. Cut-backs in British aluminum reduction plants meant reduced need for bauxite and consequent reductions in shipping space allocated to carry the ore from Takoradi to Great Britain. The high mining costs and the long rail haul from mine to port make the outlook poor for Gold Coast bauxite after the war.

Haiti.—According to reliable sources, the Ste. Croix area is said to contain at least 10,000,000 tons of bauxite. Other smaller deposits have been located, but present indications are that only the Ste. Croix area has large enough reserves of commercial ore to be exploited under present conditions. Samples of Haitian bauxite show a range of 30 to 52 percent available alumina; 21 to 25 percent ferric oxide; and 1 to 10 percent silica. The ore is said to have been formed from the weathering of limestone and is a red, friable, claylike material.

India.—The Indian Aluminium Co., Ltd. (formerly the Aluminium Production Co. of India, Ltd.), was the only active producer of ingot aluminum in India during 1944, according to reports. The output of primary metal by this company from its plant at Alwaye, Travancore, is estimated to have been about 1,600 metric tons in 1944, and reported plans are that ultimately capacity will be raised to 5,000 tons annually. In the near future the Indian Aluminium Co., Ltd., expects to begin production of alumina from a plant now under construction at Ranchi in Bihar Province. Nearby bauxite deposits will supply the raw material for the plant and are reported to have a minimum Al_2O_3 content of 52 percent and an SiO_2 content of less than 5 percent. This company also owns and operates a sheet rolling mill at Calcutta and will thus have an integrated operation upon completion of its alumina plant at Ranchi.

The Aluminium Corporation of India, Ltd., also plans to have an integrated operation in Asansol, Bengal, where its alumina plant is already in limited operation. The ingot plant and rolling mill now under construction by this company are expected to produce in 1945.

Jamaica.—Aluminium, Ltd., of Canada, through its subsidiary, Jamaican Bauxite, Ltd., is reported to have acquired important bauxite properties in Jamaica. Work has been carried on since 1942 in exploration of these deposits which is expected ultimately to lead to the development of mines and a drying plant to supplement Canada's present source of supply—British Guiana. Reynolds Metals Co. announced the development of long-range plans for mining bauxite in Jamaica, but predicted that operations were unlikely to begin until after the war. The company has acquired holdings in several parishes on the island.

Japan.—According to reports from Japan, bauxite deposits have been recently discovered in Kagawa on Shikoku Island, and the Japanese industry is reported to have begun their exploitation. The deposits are reported to have ore containing about 40 percent alumina.

Mexico.—A company known as Alumino Industrial Mejicano, S. A., has been formed by Aluminium, Ltd., of Montreal, Canada. The company has acquired land near Mexico City and is erecting an

aluminum sheet mill which will be the first part of an ultimate 5,000-ton fabricating enterprise.

Nigeria.—West African Aluminium, Ltd., was recently formed with a nominal capital of £250,000 as a subsidiary of Anglo-Transvaal Consolidated Investment Co., Ltd., to exploit bauxite deposits in Nigeria.

Spain.—Aluminum production in Spain dropped to 206 tons in 1944 owing to an acute power shortage and inability to import sufficient alumina. Official annual production statistics have been made public in *Estadística Minera y Metalúrgica de España*, Spain's official publication of metal and mineral statistics, for the first time since before the war. Normal Spanish requirements of aluminum are said to be approximately 3,500 tons a year, and thus imports have been necessary to aluminum-consuming industries in recent years. During 1944, 1,050 tons of pig aluminum were imported, in addition to some metal in fabricated and semifabricated form. Normal productive capacity of the plant of the Sabinanigo plant of Soc. General Española de Aluminio is reported to have been raised to 2,700 metric tons annually, and plans for at least one other reduction plant have been formulated but were not believed to have been carried out by the end of 1944. Top production for this country during the past decade was in 1940, when 1,295 tons of aluminum were produced.

Surinam (Dutch Guiana).—Bauxite production in Surinam decreased 62 percent in 1944, totaling 625,804 metric tons as compared with 1,655,147 tons in 1943. The Surinamsche Bauxite Maatschappij produced 83 percent of the total, or 517,707 tons, and the remaining 17 percent, or 108,097 tons, was mined by the N. V. Billiton Maatschappij. Both mines of Surinamsche Bauxite Maatschappij at Moengo, about 105 miles east of Paramaribo on the Cottica River, and Paranam, about 30 miles south of Paramaribo on the Surinam River, and the mine of the N. V. Billiton Maatschappij at Smalkalden on the Para River were in operation throughout 1944. It is understood that the Billiton mine will be closed down in 1945. Lowered exports, paralleled by decreased production, were due to reduced shipping quotas and scarcity of bottoms as well as to lessened need for bauxite in the United States and Canada. Present indications are that 1945 production will be at or near the same level as that in 1944.

Sweden.—On March 1, 1944, the Swedish Industrial Commission removed all restrictions on the sale of aluminum and its alloys, including scrap. This action reflects the improved position of the country in respect to aluminum as a result of the successful operation of the Kubikenborg alumina plant and the release of State-owned reserve of aluminum metal. Sweden is now self-sufficient in aluminum raw materials; cryolite is produced synthetically, and alumina is made from andalusite by the Pedersen process.

United Kingdom.—Early in 1945 the British Ministry of Aircraft Production announced a reduction of £25 per long ton in the price of aluminum in Great Britain. The new price is £85 and represents the first official price change since 1939, when aluminum was pegged at £110. This action brings the British aluminum price down to an equivalent of 15.3 cents per pound, based on the official Bank of England sterling rate of \$4.035, compared with the present United States price of 15 cents a pound for virgin ingot and 14 cents a pound

for pig aluminum. Announcement was made of the formation of the Aluminium Development Association, comprising alloy producers and fabricators whose objective is to develop new and expanded uses for aluminum alloys by encouraging research and disseminating information to the British public concerning the many uses to which aluminum can be put.

Production of aluminum in the United Kingdom in 1944 is estimated to have decreased 37 percent from 1943, owing to cut-backs during the year. The 1943 output of aluminum—nearly 57,000 tons represented an all-time record for the domestic industry. R. N. Cooper, chairman of the board of the British Aluminium Co., Ltd., reviewed some of the wartime activities of the company and said that the increased metal output was accomplished by completion of the Lochaber facilities, by increasing capacity at Kinlochleven, and by erecting and operating for the Government a plant using steam-generated power. The company was also associated in two other developments using transmitted power for aluminum reduction. All reduction units of the company except those at Lochaber were forced to shut down in 1944 because of the coal situation, and there does not appear to be much likelihood of their being put back in production in the near future. The company alumina plant at Newport was materially enlarged during the war period, and minor changes were made at the Burntisland and Larne plants. The rolling mills at Milton and Warrington were greatly enlarged, and heat-treating facilities for high-strength alloys were installed at each plant. In addition, an entirely new rolling mill was constructed which is reputed to be the largest in the British Isles.

Bauxite production from County Antrim in Northern Ireland in 1944 dropped to less than half of the 1943 total, owing to the aluminum cut-back in the British Isles. Supplementing this source of supply, ores were imported from Gold Coast and British Guiana in 1944.

U. S. S. R.—Russian reports indicate that a new aluminum-reduction plant and a Bayer-process alumina plant are under construction in the northern Urals near the Krasnaya Shapochka bauxite deposits at Bogoslovsk. The alumina plant and power station are said to have been virtually completed during 1944, and first production of metallic aluminum from the reduction plant is expected early in 1945. The Kamensk aluminum plant in the Urals, which began operations in 1940, is reported to have produced $2\frac{1}{2}$ times as much alumina and aluminum in 1944 as it did before the war. Originally planned ultimate annual capacity of the plant is believed to have been approximately 50,000 tons. Pravda reported that Siberian aluminum production will be greatly increased by the completion of the new plant at Stalinsk in Kemorovo Oblast, the second section of which commenced operations in 1944. Newly discovered deposits of bauxite are reported in the western Altai Mountains in Siberia.

Venezuela.—According to The Gaceta Oficial of June 9 and 10, 1944, applications for exclusive exploratory concessions in an area of 50,000 hectares in the Department of Antonio Diaz in the Federal Territory of the Delta Amacuro, believed to contain bauxite deposits, have been made in the name of Republic Mining & Manufacturing Co., a subsidiary of Aluminum Co. of America.

MERCURY

SUMMARY

The development in 1944 of a new dry-cell battery, an important component of which is mercuric oxide, resulted in requirements for mercury so large as to reverse completely the outlook for the mercury industry. This battery is described under "Consumption and Uses."

The world mercury industry is a small-quantity business. The sources of supply are relatively concentrated, and usually they are largely cartel-controlled. Price does not enter into the determination as to whether or not the metal will be used in most instances. For many uses the efficiency of mercury leads to its continued demand even when supplies are difficult to obtain. The mercury industry is volatile from an economic viewpoint largely because of the conditions outlined, and its history during the war period bears out this assertion. In the United States mercury was the first strategic metal to complete the cycle from scarcity to plenty. The prospective gains in demand in the United States and the expected divorce of the United States from its usual sources of supply, because of shipping difficulties, led to the near tripling of the domestic prewar price by June 1940. The next 3 years witnessed sharp increases in production in the United States and its neighbors, Canada and Mexico, consumption restriction, price control, and Government-purchase contracts. War planning for the mercury industry was more than well done, with the result that by the end of 1943 the market faced near-record supplies, a rapidly diminishing consumption, and a declining price structure supported only by Government-purchase contracts.

At the outset of 1944 the outlook for the domestic mercury producer was gloomy. Government purchases were discontinued in January, the Government submitting to the requirement for making certain penalty payments for contract cancellations, as described in the chapter on mercury, Minerals Yearbook 1943. Production dropped notably in February and continued downward, almost without interruption, until the low point of 2,300 flasks was reached in

November, the lowest monthly rate since February 1940. Consumption amounted to less than domestic production beginning September 1943 and continued below it until June 1944. During this period the Consumption Restriction Order M-78, eased in September 1943, was rescinded (in February 1944). In July mercury was removed from the list of materials that were subject to the restrictions of General Import Order M-63. Beginning in August the effects of the demand for mercury for the manufacture of the new dry-cell batteries began to be felt, and consumption rose to 3,900 flasks, at which rate it continued for the remainder of the year. The explanation for the lagging rate of gain is twofold, i. e., the battery use rose in the final quarter of the year, whereas other uses declined, leaving the total unchanged, and some difficulties that were involved in battery manufacture interfered with the expected degree of the advance.

In the second half of 1944 consumption amounted to almost 1½ times as much as production. Imports during 1944 amounted to only 41 percent of those for 1943, and only 40 percent of the reduced tonnage entered the country during the latter half of the year. The Metals Reserve Company contract with the larger Canadian producer, the Consolidated Mining & Smelting Co. of Canada, Ltd., had been canceled in September 1943 and shipments against Mexican contracts, scheduled to be completed in July 1944, were permitted to be made subsequent to July with the total quantity involved unchanged. The contract with Bralorne Mines, Ltd., Canada, was canceled in September. In the late months of 1944, therefore, the importation of mercury had been largely restored to private hands.

Salient statistics of the mercury industry in the United States, 1940-44

[Flasks of 76 pounds]

	1940	1941	1942	1943	1944

¹ Large amounts were reexported in 1942 and 1943 (see section on Foreign Trade).

The low point in prices was reached in July, when the monthly average amounted to less than \$101 a flask, or to little more than half the annual averages for 1942 and 1943. The sharp reductions in supplies of mercury in the United States from domestic and foreign sources, coupled with the upturn in consumption, beginning in August, and with the anticipation of considerably greater gains throughout 1945, were responsible for growing concern on the part of consumers regarding their ability to obtain enough metal to fill their needs. As requirements outstripped demand, the price advanced. It averaged \$129 a flask in December, and the uptrend was far from halted at that point. By the end of November, industry stocks were at their lowest

levels since the Bureau of Mines monthly canvass began in September 1939 and for an indeterminate period before that, and spot metal was difficult or impossible to obtain. The War Production Board took cognizance of the growing seriousness of the situation by announcing on December 1 that the Metals Reserve Company, at the recommendation of the War Production Board, would release mercury from the Government stock pile for filling current war and essential civilian needs.

Thus, unforeseen developments reversed the conditions of oversupply in the mercury industry during the year. The same statement may be made concerning numerous other commodities, but, as in creating sufficient supplies first, mercury again was ahead of most others. Its unbalance came before the set-back, in the fall, to Allied hopes for an early end to the European phase of the war.

Metals Reserve Company's domestic purchases.—The discontinuance of domestic purchases by the Metals Reserve Company at the end of January 1944 and the penalties involved thereby were described in the report of this series for 1943.

General Import Order M-63.—Imports of mercury were subject to the limitations of M-63 beginning December 28, 1941. In July 1944, when supplies of mercury appeared to be ample for all emergencies and when the problem appeared to be more one of surplus than of deficiency, mercury was removed from the list of products that were under control of the import order.

Surplus Property Act.—The passage of the Surplus Property Act, effective October 3, relieved anxiety regarding surpluses that were expected to be on hand at the end of the war. The act provided that all Government-owned accumulations of certain strategic minerals and metals, of which mercury was one, when determined to be surplus, should be added to the permanent Government stock pile authorized by the act of June 7, 1939.

Releases of mercury from Metals Reserve Company stock pile.—The situation created by the rapid increase in demand for mercury due to the production of a new mercury battery has been described already. The War Production Board moved to remedy a critical supply situation by announcing, on December 1, that the Metals Reserve Company, upon recommendation of the War Production Board, would release mercury from the stock pile for current war and essential civilian needs. The metal was released at \$2 a flask above the quotation in Metal and Mineral Markets on the Thursday subsequent to the execution of the contract.

The indications are that there was a sharp reduction also in world production outside of the United States. Western Hemisphere sources were affected by expanding supplies in the United States at the beginning of 1944, which led to the cancellation of Metals Reserve Company's contracts or their failure of renewal; Chile's contract, however, ran shortly beyond the end of the year. Canadian production dropped 57 percent and Mexican 7. Precise data for Spain and Italy are not available, but output in the former was reported to be at a greatly reduced rate because of large stocks, and that in the latter was affected adversely by the fighting that took place in the most productive area.

Geological Survey and Bureau of Mines activities.—The Geological Survey had completed most of the necessary field work in its study

of all major quicksilver deposits in the United States by the end of 1944. Field work now in progress consists of areal mapping in the New Almaden quicksilver district, Santa Clara County, Calif.; completion of studies of the Oregon deposits; and a detailed study of the deposits at Steamboat Springs, Nev. Field work on the Terlingua district, Texas, and Oat Hill mine, Lake County, Calif., has been completed, and reports on these districts are in the process of preparation.

The California Division of Mines expects to publish a comprehensive bulletin on quicksilver deposits of California, using reports by the Geological Survey on the following districts: Panoche, Knoxville, East and West Mayacmas, New Idria, Guerneville, Cachuma, and Sulphur Bank. The report published by the Nevada State Bureau of Mines on quicksilver deposits in Nevada is now available.¹

Announced by press releases were the availability of maps and brief text descriptions of the Harry Area, New Almaden mine, Santa Clara County, Calif.; 248 mine, Terlingua district, Texas; Mariposa mine, Terlingua district, Texas.

The Geological Survey continued investigations of Alaskan quicksilver deposits during 1944. Deposits near the abandoned village of Kolmakof in the central Kuskokwim region were examined in detail in conjunction with trenching operations by the Bureau of Mines. The basins of the Wloyukuk and Oskawalit Rivers were explored, and formations favorable for the occurrence of quicksilver were discovered along the latter stream.

Field work on the study of mercury resources of Mexico was completed by the Geological Survey under the auspices of the State Department, and two reports resulting from these studies are in process of publication. A study of the mercury resources of Chile was made, and the results of this investigation also are in the process of publication.

The work of the Bureau of Mines in the exploration of mercury deposits and the results obtained up to June 30, 1944, were summarized by Mosier.²

The results included a total of 40,307 feet of drilling, 33,082 linear feet of surface trenching, with ore reserves indicated as 389,600 tons of commercial ore containing an average of 7.4 pounds of mercury per ton and 1,008,000 tons of marginal ore containing 2.2 pounds per ton. The report states that the equivalent mercury in the reserves indicated was 37,400 and 29,200 flasks, respectively, or a total of 66,600 flasks. As of June 30, the Bureau had examined 190 deposits, as follows: Alaska, 3; Arizona, 9; Arkansas, 31; California, 38; Colorado, 2; Idaho, 16; Michigan, 1; Nevada, 43; New Mexico, 1; Oregon, 27; South Dakota, 1; Texas, 11; Utah, 2; Washington, 3; and West Virginia and Wyoming, 1 each. Fifteen exploratory projects were started after these examinations, and 13 had been completed by June 30.

War Minerals Reports were prepared for limited distribution on the following properties in 1944: Alice and Bessie mine, Sleitmut area, Alaska; Decoursey Mountain Mercury deposit, Iditarod district, Alaska; mercury deposits, Pike County, Ark.; New Idria mine, San

Benito County, and New Almaden mine, Santa Clara County (supplement to report completed May 1943), Calif.; and Terlingua mercury district, Brewster County, Tex. (supplement to report made in December 1942).

POSTWAR OUTLOOK

Developments in 1944 have caused a marked change in the outlook for mercury. The question as to what place the new dry-cell battery, which employs mercury, will have in the future is so important that its answer should indicate whether or not postwar consumption levels will be similar to or higher than they were in the prewar period. Beginning in 1945, for example, the war needs for the new battery are expected to take much more mercury than all other uses combined. The battery's proponents anticipate that it will have large industrial application after the war, and some of the suggested uses are hearing aids, fire-alarm equipment, and portable radio sets. Considerable research probably will be required before the battery can be assured of a substantial market, and the pressure for speed in supplying war demands has interfered with carrying on adequate research work. Other uses for mercury are expected to follow the pattern outlined briefly in the chapter of this series for 1943. How much of the total postwar consumption, which should be at prewar or higher levels, will be supplied by domestic mines will depend largely on price, and the price will be determined, in part, by the Government's attitude on the continuation of the tariff on mercury. With a large postwar demand and the protection of the tariff of \$19 per flask, it is probable that most of the present larger domestic producers would aid in supplying requirements for mercury after the war. A sharp decline in prices, such as followed World War I, however, would close all but a very few domestic mines. A low postwar price would return the task of supplying world mercury needs largely to Spain and Italy.

PRICES

Prices for mercury in 1944 clearly mirrored the rapidly changing conditions of supply in this industry. The average quoted price had remained at the level of \$196 a flask (76 pounds) in New York from the last week in October 1942 to the last week in September 1943. Easing conditions of supply at the end of that period brought with it a declining price. By the end of the year, the quotation had dropped to a range of \$190 to \$193, but much of the production at that time and during January was being purchased by the Metals Reserve Company. As has been indicated in this report, purchases of the Metals Reserve Company ceased at the end of January. In January 1944 the monthly average was \$152, but the price range at the month end was \$130 to \$140. The downtrend continued until a monthly average of \$101 was established in July. The July average was only half that for January 1942, the last month before the Government established ceiling-price limitations. The revised supply-requirements situation in the fall of 1944, described in the opening section of this report, caused an upturn in prices that continued beyond the end of the year. In December the monthly average was \$129 a flask, but at the end of the month the quotation was \$140 to \$145, and the trend continued upward another month until offerings of Spanish mercury in New York for future delivery dampened the ardor of purchasers.

Average monthly prices per flask (76 pounds) of mercury at New York and London, and excess of London price over New York price, 1942-44

¹ Engineering and Mining Journal, New York.

² Mining Journal (London) prices in terms of pounds sterling are converted to American money by using average rates of exchange recorded by Federal Reserve Board. Official prices, established early in May 1941, were £47 15s. to £48 15s. per flask until August 1942, when they were raised to £68 10s. to £69 15s.

³ New York excess.

Control maximum prices in London remained unchanged from those during the late months of 1942, at £69 15s. a flask for over 1 flask and less than 11 flasks and £69 for larger amounts, ex-sellers' premises in both cases. Higher prices prevailed for lots under 1 flask and for redistilled grades.

CONSUMPTION AND USES

Consumption and uses of mercury were outlined broadly in the report of this series for 1943. Since that report was prepared, an outstanding change has taken place, the potentialities of which cannot be gaged as yet. The successful production of the new dry-cell battery previously mentioned was begun in 1944, and the use of mercuric oxide as a principal ingredient has had a profound effect upon the outlook for mercury. The new battery cell is encased in a steel can, which is used as the positive pole in creating an electric current. Mercuric oxide and layers of zinc and paper, especially prepared, are arranged to fit into the container in a spiral, like a "jelly roll." A zinc pellet at the top of the can, but insulated from the steel, serves as the negative pole. The chief value of the cell is said to be its ability to stand up under high temperatures and high humidity. Other features of the battery are its long shelf life, its ability within its rated current range to deliver the same ampere-hours service whether operated intermittently or continuously, and its much greater power for the size of unit used. This battery was developed by P. R. Mallory & Co., Inc., which controls the patents for its use.

Consumption of mercury for the new battery in 1945 is expected to exceed that used for all other purposes combined. These heavy war demands have interfered with carrying on adequate research into the postwar possibilities for the battery, as indicated in the company's statement to stockholders, dated February 5, 1945, as follows:

It is still too early to hazard any fair appraisal of the peacetime significance of this development. At the moment, all effort is concentrated on increased production to meet expanding military requirements.

Supply of mercury in the United States, 1940-44, in flasks of 76 pounds

¹ The items are on a partial-coverage basis and do not add to the total, which has been increased to cover approximate total consumption.

² Revised.

³ About half of the quantity shown under "Redistilled" was for use in industrial and control instruments.

⁴ A large part of the total was for chemical-warfare purposes.

STOCKS

Consumers and dealers held 10,400 flasks of mercury at the end of 1944, compared with 13,200 at the beginning of the year, or a decrease of 21 percent. Companies that account for more than 95 percent of the total production held 2,714 flasks at the end of 1944, compared with 3,457 at its beginning. It should be borne in mind that the inventory data of the Bureau of Mines are on a physical rather than an ownership basis. Total industrial stocks gained in December. At the end of November, however, when they aggregated 9,900 flasks, they were the smallest on record since the Bureau of Mines inaugurated monthly surveys on mercury, in September 1939, and probably for a substantially longer period. At the end of 1944, some mercury that had been sold under the recent order for releasing metal from the stock pile was still held by the Metals Reserve Company, but it was not counted as part of their inventory. Inasmuch as industry stocks are on a physical basis, an unmeasured amount of mercury was not accounted for at all in the total year-end inventory.

REVIEW BY STATES

As was pointed out in the opening section of this report, the outlook for the domestic producer was gloomy at the outset of 1944. In

October 1943 the War Production Board announced that its aim was to reduce domestic production and imports in 1944 each to 70 percent of the 1943 quantities. Purchases of the Metals Reserve Company were to cease at the end of January 1944, and prices were already declining rapidly. It is merely a coincidence, however, that production of mercury in 1944 came so close to the proposed reduction of the War Production Board, or to 73 percent of the 1943 total, because after midyear 1944 the demand for mercury increased and prices headed upward, beginning in July. Production totaled 4,400 flasks in January when producers were trying to build up as high a production rate as possible, against which Metals Reserve Company contract-cancellation penalty payments would be made. After the outlook improved and prices rose, there was relatively little change in the rate of production, as shown in the table that follows. Perhaps the plunge in prices from late 1943 to July 1944 was too fresh in producers' minds.

¹ Value calculated at average price at New York.

The 27-percent drop in production for the country was not shared in equally by the contributing States. Production in California, for example, declined only 17 percent. Arkansas, on the other hand, experienced a drop of 88 percent. Idaho, where the country's second largest 1943 producer was idle for several months, had the next most severe drop; Nevada fell 46 percent; Texas, 38 percent; and Oregon, 32 percent.

The principal producing mines in 1944 were as follows:

Alaska—Red Devil and Decoursey Mountain mines.

Arizona—Gila County, Ord mine; Maricopa County, Pine Mountain mine.

California—Contra Costa County, Mount Diablo mine; Lake County, Abbott, Mirabel, Sulphur Bank and Helen mines; Napa County, Oat Hill and Knoxville mines; San Benito County, New Idria mine; San Luis Obispo County, Klau and Buena Vista (Mahoney) mines; Santa Barbara County, Falcon (Santa Ynez) mine; Santa Clara County, New Almaden and Guadalupe mines; Sonoma County, Mount Jackson and Culver-Baer mines; Trinity County, Altoona mine; Yolo County, Reed mine.

Idaho—Valley County, Hermes mine.

Nevada—Esmeralda County, Red Rock mine; Humboldt County, Cordero mine; Pershing County, Pershing and Red Bird mines.

Oregon—Douglas County, Bonanza mine; Jefferson County, Horse Heaven mine.

Texas—Brewster County, Chisos-Waldron, Big Bend, and Texas Almaden mines; Presidio County, Fresno mine.

These 31 mines in 1944 produced 97 percent of the United States total; in 1943, 28 mines contributed 90 percent, and in 1942 it took 34 mines to produce 89 percent.

Of the larger mines in 1943, the Humphreys and United States Mercury Co. properties in Arkansas, the Socrates in California, and the Silver Cloud in Nevada were dropped from the list, whereas the following found places thereon: Decoursey Mountain in Alaska, Pine Mountain in Arizona, Helen, Culver-Baer and Altoona in California, Red Rock in Nevada and the Chisos-Waldron in Texas. Approximately half of the principal mines listed for 1944 were idle in December, most of which appeared to have no immediate plans for reopening.

As a consequence of lower prices in 1944 the average recovered grade of ore treated rose. It was 0.47 percent (9.4-pound ore) in 1944, compared with 0.31 percent (6.28-pound ore) in 1943 and 0.25 (5-pound ore) in 1942. The 1944 average was the highest on record since 1926, when the recovered grade was 0.54 percent (10.8-pound ore). The grade was raised in 1944 by the closing of many low-grade properties and by the mining of higher-grade areas in properties that remained in operation.

Alaska.—Mercury was produced in 1944, as in 1943, in the Sleitmut and Decoursey Mountain areas, the 1944 output exceeding that for 1943. All metal from both the Red Devil (New Idria-Alaska) and the Decoursey Mountain properties went to Metals Reserve Company depots, and both properties closed when contracts with that organization were completed. The furnace at the Red Devil mine was closed on April 10, after which production from clean-up operations was continued by retort into June. Decoursey Mountain also closed in June.

Arizona.—Productive operations were carried on at three Arizona properties in 1944: The Ord mine in the Brown district, Gila County, and the Pine Mountain and National mines in the Sunflower district, Maricopa County. Furnaces were used at all three locations, and a

retort for higher grade ore also was used at the Ord mine. The 60-foot Gould rotary furnace at the National mine was installed in 1943, and a new Cottrell rotary was reported erected there in 1944.

Arkansas.—The mercury industry in Arkansas came to a virtual standstill in 1944. After producing over 1,100 flasks a year for 4 years and well over double that amount in 1942, output dropped to only 191 flasks in 1944. The Humphreys mine in Clark County made a relatively large production in 1943. It was the largest producer again in 1944, with an output of 72 flasks, despite the fact that it closed on February 20. Other producers in Arkansas in 1944, all in Pike County, were the property of the Arkansas Quicksilver Mines, Inc., Muddy Fork, Hintze, Wall Mountain, and three smaller contributors.

California.—Production of mercury in California was bolstered by the continued high rate of production at the New Idria mine and by the gains of 92 percent in output for the Reed and 93 percent for the Abbott. As a consequence, the output for the State amounted to 28,052 flasks, compared with 33,812 in 1943, or a decline of only 17 percent, compared with a loss of 27 percent for the country as a whole. Important 1943 producers that showed noteworthy losses in 1944 include the Mount Diablo, Sulphur Bank, Oat Hill, Klau, and Falcon mines.

Sixteen counties contributed some production in 1944, as follows: Contra Costa, Del Norte, Fresno, Inyo, Lake, Mono, Monterey, Napa, San Benito, San Luis Obispo, Santa Barbara, Santa Clara, Sonoma, Stanislaus, Trinity, and Yolo.

The Mount Diablo mine in Contra Costa County was a producer of substantial amounts of mercury in the first half of 1944, but production was suspended in August.

A small production was made in a 2-ton inclined retort at the Patricks Creek mine, Del Norte County. A small contribution also was made by a property in Fresno County.

In the first half of 1944, production was reported for the King (Coso) and Atlas mines, Inyo County. No production is believed to have been made from June until the end of the year.

Lake County was second only to San Benito as a mercury-producing area in the United States. Its output totaled 3,776 flasks, which were recovered from 17,770 tons of ore. The Abbott mine was the most important producer in the county with a production gain of 93 percent over 1943. It ranked third in the country compared with ninth in 1943, which position was a substantial improvement over the year before. The Mirabel, Sulphur Bank, and Helen mines ranked next in order, and each produced more than 100 flasks. Other producing mines in the county were the Bullion (Otto), Great Western, and Thorne. All of the ore was treated in furnaces except that from the Thorne, which was treated in a retort.

Development by diamond drilling was reported at the Occidental mine, Mendocino County, where the furnace was undergoing repairs.

The Paramount mine, Mono County, produced a small amount of mercury in 1944, but closed in January owing to the discontinuance of the Metals Reserve Company's purchase program. Production was made in a furnace that was reported to have been removed from the property in the latter half of the year.

The output of 1,203 flasks of mercury in Napa County in 1944, of which 1,167 flasks were from the treatment of 23,990 tons of ore,

made this the sixth-ranking county in the State. Production was chiefly from the Oat Hill and Knoxville mines. At the Oat Hill mine 13,280 tons of ore were treated in a 4-by 60-foot rotary furnace, and 588 flasks of mercury were recovered. The company reported that operations were suspended on July 1 and the equipment was being dismantled. Gamble & Wilson treated 7,712 tons of ore in a 3-by 40-foot rotary furnace at the Knoxville mine and produced 463 flasks of mercury. Operations there were closed September 30. Subsequently a small output was reported to have been made by another operator. Other producers in 1944 were the Oat Hill Extension, Eureka No. 3 dump, Manhattan, James Creek placer, Aetna, and Corona properties.

San Benito County was the most important mercury-producing county in the United States in 1944. This preeminent position was due, of course, to the output of the New Idria mine, which produced more mercury than the next four largest producers in the country. The closing of the Consolidated property in British Columbia caused New Idria to be the largest producer in the Western Hemisphere also. San Benito County produced 12,374 flasks in 1944, compared with 14,187 in 1943. Except for the New Idria mine, there was no large producer in the county. Production was reported for the Lea-Grant, Stayton, and eight smaller operations. A recent court decision³ determined in New Idria's favor the contention that percentage depletion be computed on the gross sales of the first marketable product and also that depletion be allowed on material mined from old dumps.

There was a sharp drop in production of mercury in San Luis Obispo County in 1944, when 943 flasks were produced, compared with 2,618 flasks in 1943. The termination in April of mining operations at the Klau mine, the largest producer since 1939, was the chief reason for the poorer showing. The company reported that lower prices and the shortage of labor, which impeded development, were the causes of the cessation of operations. The plants were said to be largely dismantled. A total of 4,092 tons of ore was produced and furnaced, and 453 flasks of mercury were produced before the close-down. The Buena Vista mine was the second largest producer. It was leased by E. Julian Phillips until November 4, after which it was leased by Virgil Smith, both of whom produced. Two operators also produced at the Oceanic mine. The Oceanic Mining Co., operating in the latter part of the year, reported closing October 4 because of the labor shortage. Lawrence Requa, producing at the Polar Star mine, stated that the operations were discontinued, the plant dismantled, and the property returned to the owners as of May 29. The Buckeye mine and two others complete the list of producers in the county.

Three properties in Santa Barbara County produced in 1944, the principal one being the Falcon (Santa Ynez) mine, which was productive through July. The others were the Red Rock and the Lion Den.

The New Almaden mine was again by far the largest producer in Santa Clara County. Total production for the county amounted to 1,699 flasks, compared with 1,729 flasks in 1943 and 2,283 in 1942. Shortage of labor impeded operations at the New Almaden mine, and production was reduced as compared with 1943. Operation of the recently installed Gould rotary furnace at the Guadalupe mine re-

³ *Mining Congress Journal*, vol. 30, No. 11, November 1944, pp. 21-23.

sulted in a noteworthy gain in production at this property. The furnace was recently described briefly.⁴

Production in Sonoma County in 1944 was dominated by the Mount Jackson mine, as it had been for several years. The total for the county amounted to 2,878 flasks in 1944, indicating a noteworthy decline from 4,111 in 1943 and 4,114 in 1942. The Culver-Baer ranked second in 1944. Rotary furnaces were used at the foregoing mines, and retorts were used at the other productive properties, including the Socrates (clean-up), Buckeye, Wild Hog, and Dewey Geyser Mercury Mines. The Mount Jackson mine was described recently.⁵

A small amount of mercury was recovered from clean-up operations at the Adobe mine, Stanislaus County.

In 1944 the Altoona mine, Trinity County, ranked as the ninth largest mercury-producing mine in the United States. Its output was several times that for the year before. Operations were suspended November 15 for the winter season. There was no other producer in the county.

The second largest mercury producer in the United States in 1944 was the Reed mine, Yolo County, the only active mercury property in the county. It was one of the few important mercury producers in the country to increase its output in 1944, the rise amounting to 92 percent.

Idaho.—The Hermes mine, Yellow Pine district, Valley County, was the only mercury producer in Idaho in 1943, when it ranked as the second largest producer in the country. The Hermes mine produced during every month in the first half of 1944 but closed in June. After the demand for mercury improved, production was resumed in November, but a labor shortage impeded large-scale operations. The Hermes placed seventh among the mercury-producing mines of the country in 1944 with a production of 1,332 flasks from 11,409 tons of ore. A small production of mercury was made by the Lackey mine in Washington County in 1944.

Nevada.—Output in Nevada was cut virtually in half in 1944, dropping from 4,577 to 2,460 flasks, or 46 percent. Noteworthy declines were reported by the Silver Cloud, Red Bird, and Pershing mines. The Cordero mine continued as the outstanding producer in the State and ranked sixth among producers in the United States.

The Silver Cloud mine, Ivanhoe district, Elko County, produced in January and the first days of February. The lease was subsequently canceled. A few flasks also were produced from clean-up operations at the Velvet mine in the same district.

The Red Rock mine, Oneota district, Esmeralda County, was in production during the latter part of the year only. Production amounted to 124 flasks from 415 tons of ore treated in a Gould rotary furnace.

Production of mercury in Humboldt County in 1944 was largely from the Cordero mine, which was the largest producer in Nevada and the sixth largest in the country. Production is made in a 125-ton Herreshoff furnace. Rehabilitation of old works and development of new ore bodies were reported to be the chief activities at the Cahill mine, which produced 32 flasks during the year. The Blackrock mine

⁴ Engineering and Mining Journal, Guadalupe Mercury Mine Has New Treatment Plant: Vol. 45, No. 6, June 1944, p. 86.

⁵ Mining World, vol. 6, No. 6, June 1944, p. 45.

also produced, but it closed in the spring of 1944. Construction of a new plant and development were reported at the Blue Bucket mine in 1944, but there was no production.

Four operators produced small amounts of mercury in Mineral and Nye Counties in 1944.

Pershing County was the source of 685 flasks of mercury in 1944, compared with 1,749 flasks in 1943. There were seven productive mines in 1944, compared with 11 in 1943. The largest producer in both years was the Pershing mine in the Antelope Springs district. This property ceased all operations on June 1, and plant machinery and equipment were reported sold to a machinery dealer. Other productive mines were the Red Bird, Goldbanks, Vermilion, and three smaller ones. Production of the first three properties was made in furnaces and that of the others in retorts. The Goldbanks ore was trucked over 100 miles to the Opalite mine, across the State line in Oregon, for treatment.

Oregon.—Oregon ranked second among the mercury-producing States in 1944, a position it has held continuously since 1936. Production amounted to 3,159 flasks, or a decline of 32 percent from 1943, and it was equivalent to only 35 percent of the outputs for 1940 and 1941. The Bonanza mine, Douglas County, experienced no difficulty in maintaining first place among producing properties in Oregon in 1944; in the United States it dropped to fifth from third place. Its production of 2,426 flasks in 1944 came from 15,547 tons of ore.

The high-grade Maury Mountain property and three other small producers supplied the total output of Crook County. The furnace and other equipment at the Blue Ridge mine was reported to have been sold in 1943.

As usual, in 1944 the Horse Heaven mine ranked second among the mercury-producing properties of the State. Production at this property declined in 1944, but it rose to tenth rank in the country, nonetheless, because of greater decreases at some other large mines. A fire at the mine on November 22 destroyed the furnace, power plant, and other structures.

Small production from clean-up operations was reported for the Bretz and Opalite mines, Malheur County, in 1944. Press reports indicated that a contract had been awarded late in the year for deep churn drilling at the Opalite property.

Texas.—In common with other areas, Texas production dropped notably in 1944, or to 1,095 flasks from 1,769 flasks in 1943. Again the output came from Brewster and Presidio Counties. The Fresno mine, Presidio County, ranked first in the State by a narrow margin; its production amounted to 485 flasks from 5,918 tons of ore in the first 8 months of the year during which it was productive. It closed because of the low price for the metal, and no labor was available when prices improved.

The Esperado Mining Co. operated the Chisos and Waldron mines, Brewster County, as a unit in 1944 and made the second largest contribution for the State, with an output of 481 flasks from 11,816 tons of ore and tailings. The Big Bend and Texas Almaden properties, which stood first in 1943, operated in 1944 only in January. One other property had a small output in 1944.

FOREIGN TRADE⁶

Imports of mercury for consumption in 1944 fell 59 percent from the record high rate established in 1943, or from 47,805 flasks to 19,553 flasks. This drastic drop is explained by the cancellation by the Metals Reserve Company of its contracts with most foreign producers during the year; the contract with the Consolidated Mining & Smelting Co. of Canada, Ltd., was terminated in September 1943, and that with Chile ran to January 31, 1945. As a consequence of the earlier termination of the Consolidated contract, and despite imports from Bralorne Mines, Ltd., that did not start until 1944 and ceased in September, receipts from Canada registered the largest drop, or 90 percent. Chile supplied 63 percent less mercury, Peru 52 percent less, and Mexico 42 percent less. It was pointed out in the report of this series for 1943 that imports for 1943 and 1942 give a false idea of the amounts of mercury entered for use in the United States. Imports of mercury for consumption were reported as 38,941 flasks in 1942 and as 47,805 flasks in 1943. This mercury was entered for the account of the Metals Reserve Company. Totals of 7,461 and 14,852 flasks, respectively, were reexported in 1942 and 1943. In relation to the figures for earlier years, therefore, the import totals for 1942 and 1943 are too high. From available information it is not possible to assign the totals reported to the countries of origin.

General imports, which may differ considerably from imports for consumption, have been very similar thereto during the war period. In 1944 general imports totaled 19,819 flasks and in 1943, 47,836 flasks. The 1944 total was supplied by the following countries (comparisons with 1943 given in parentheses): Canada, 1,564 (15,582); Chile, 982 (2,660); Mexico, 17,221 (29,487); and Peru, 52 (107).

The movement of antimony-mercury concentrates to this country, which yielded an average of over 1,200 flasks annually for 1940-42, inclusive, was halted in December 1942. This class of imports was not shown separately in foreign-trade statistics.

Mercury imported for consumption in the United States, 1940-44, by countries

¹ 567,059 pounds were reexported in 1942 and 1,128,727 pounds in 1943. These amounts cannot be separated by countries of origin.

⁶ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

No imports of mercury compounds were recorded in 1944, and only 15 pounds of vermilion red were entered in 1943.

Exports of mercury almost doubled in 1944, but even so they did not represent an important quantity; they approximated 4 percent of total imports for the year. The total for 1944 was 747 flasks, compared with 384 in 1943. The amounts exported in 1944 (comparison with 1943 in parentheses) were as follows: Brazil, 227 (89) flasks; Australia, 110 (2) flasks; U. S. S. R., 71 (66) flasks; and the remainder to 48 others, with no other country receiving as much as 40 flasks. Distribution by continents was as follows: South America, 295 (128) flasks; Oceania, 116 (20); North and Central America, 109 (61); Europe (including U. S. S. R.), 103 (66); Asia, 79 (79); and Africa, 45 (30).

Mercury exported from the United States, 1940-44

Year	Pounds	Value	Year	Pounds	Value
1940.....	730,877	\$1,743,149	1943.....	129,236	\$88,842
1941.....	196,837	470,903	1944.....	56,755	123,746
1942.....	126,252	76,448			

1567,059 pounds were reexported in 1942 and 1,128,727 pounds in 1943. These amounts cannot be separated by countries of origin.

Mercury salts exported in 1943 and 1944 are shown in the following table:

Mercury salts exported from the United States, 1943-44, in pounds

WORLD PRODUCTION

Satisfactory world-production totals for the past several years continue to be unavailable. There is little doubt that high record rates were established in 1941 and again in 1942 or that production declined in 1943 and again, more sharply, in 1944; the 1944 rate may have been less than two-thirds of that for 1942. The recent drastic drop is explained by reduced production in Spain because of the large stocks held there, by the moving of the battle area in Italy through the principal mercury-producing district, and by the belief that a surplus supply situation had developed in the United States, which caused reductions in Government purchases of Mexican, Canadian, and domestic mercury.

World production of mercury, 1938-44, by countries, in flasks

Canada.—The uptrend of mercury production in Canada was reversed in 1944, when total output amounted to only 9,682 flasks, compared with 22,240, the all-time peak, in 1943. The sharp decline in 1944 is explained by curtailment and discontinuance of production by the Consolidated Mining & Smelting Co. of Canada, Ltd., whose 1943 production made it the largest producer in the Western Hemisphere in that year. Its contract with the Metals Reserve Company was terminated in October 1943, and its ability to produce far exceeded the needs of the Canadian consuming industry. The mine was closed in July 1944, according to the company's annual report, because of the falling demand for mercury and the urgent need for labor at the company's Kimberly operation. The Metals Reserve Company contract with Bralorne Mine, Ltd., ran until September 1944, when that company's newly developed property closed.

In connection with the cessation of mercury production in 1944, Sargent⁷ stated that:

Interesting possibilities of future production remain, as factors other than costs influenced the suspensions, and it might be expected that production would be easier when supplies, machinery and personnel are available more readily than under war conditions.

The Pinchi Lake plant of Consolidated Mining & Smelting Co. of Canada, Ltd., was described recently.⁸

The following figures on consumption of mercury in Canada by uses were taken from the report of the Dominion Bureau of Statistics for 1943 on miscellaneous metals:

⁷ Sargent, Hartley, A Review of the Mining Industry in British Columbia: Western Miner, vol. 18, No. 4, April 1945, p. 51.

⁸ Canadian Institute of Mining and Metallurgy Bull., Pinchi Lake Mercury Reduction Plant: Vol. 48, No. 393, January 1945, pp. 13-26.

Italy.—Italy surrendered to the Allies in 1943, but the delayed expulsion of the German Army from the section north of Rome denied the benefits of Italian mercury to the Allies during much of 1944. The principal Italian production in recent years has come from the Monte Amiata district, about 75 miles north of Rome, Siena and Grosseto Provinces, where the chief mines are the Abbazia San Salvatore and the Solforate del Siele. When the Germans withdrew from the Monte Amiata district in 1944, only the Abbazia was seriously damaged. The surface plant was completely destroyed, but the main hoist and much portable equipment were saved. Since liberation, some of the furnaces have been rebuilt and put into operation beginning in September. Operations in the district were handicapped mainly by a severe shortage of power, minimum operations only being possible at Abbazia, pumping and partial maintenance at Siele, and nothing at all at Argus, which buys all of its power. The Argus mine was not molested by the Germans, but it sustained damage to both plant and shaft through other means. The Cerreto Piano mine, also in the Monte Amiata district and associated through ownership with the Siele, was not damaged, but it lacks power for either production or maintenance operations. Under the power conditions that prevailed early in 1945, Abbazia can produce 1,200 flasks a month. The output of the district can be expanded readily to 3,400 flasks if additional power can be made available. The Idria mine, while in German hands, was flooded and otherwise sabotaged by the Yugoslav Partisans early in 1944.

In the event that postwar world requirements for mercury are expanded above the prewar level, Italy can increase previous production rates substantially by installing additional furnace capacity. The mineralized area of the Monte Amiata district is large, and previous requirements have been insufficient to make it worth while to search for and develop new mines. The principal mines occupy a north-south belt about 20 miles long and 5 miles wide, but one active mine, the Cerreto Piano, is 20 miles southwest of this belt, and several inactive mines and prospects are well outside of the main zone. The entire district is more than 500 square miles in area. There is difference of opinion concerning reserves in the Idria deposit, which are variously reported as substantial though declining in quantity and grade and as relatively near exhaustion.

Mexico.—David Gallagher, of the United States Geological Survey, who has been in Mexico during the past 3 years, delivered a paper on the geology of the principal mercury mines of Mexico before a meeting of the United States Section of the Pan American Institute of Mining

Engineering and Geology, February 28, 1945. He observed that small operators, known as "gambusinos," had multiplied rapidly under the stimulus of high prices beginning in 1940, and that for 1940-42 their production furnished about one-half of the national total. Their crude methods, small capital, and lack of technical knowledge, however, resulted in a high rate of failure, and by 1943 most of the mercury produced was coming from larger mines in six major producing districts. The largest single producer in each of three of them was still active in early 1945.

Cinnabar is widely distributed in Mexico, he said, and is reported to occur in over 200 localities scattered throughout two-thirds of the States of Mexico. The following descriptions are quoted from his paper:

In a broad way the mercury deposits of Mexico can be divided into two major geologic classes: (1) Deposits in rhyolitic volcanic rocks, and (2) deposits in other rocks, mostly sedimentary rocks. The deposits in rhyolite are most numerous, but they are comparatively small, and very similar. In contrast, the deposits in sedimentary rocks are all different, and though few in number they include most of the large mines.

The six major districts are Huitzucó, Huahuaxtla, Nuevo Mercurio, Cuarenta, San Alto, and Canoas.

Huitzucó district.—The Huitzucó deposit, mapped by James F. McAllister of the U. S. Geological Survey, is situated in Guerrero, one of the southernmost States in Mexico. It was discovered in 1869, and had yielded a total of about 72,000 flasks of mercury and a large amount of antimony before being closed down early in 1944. It is famous as the only known large deposit of livingstonite, a rare mercury-antimony sulfide. The deposit is in limestones that were mildly folded, but much faulted and brecciated. After the limestone had been deformed it was invaded by biotite granite, and extensively replaced by dolomite and anhydrite. Later, some gypsum was formed by weathering, and deep solution holes were formed, which were filled by terrace alluvium that covered the region. Livingstonite and stibnite were deposited in the anhydritized limestone and in the gravel fill in the solution cavities. All the cinnabar is believed to be secondary after livingstonite. In the largest mine, called La Cruz, ore was mined to a depth of 770 feet, and diamond drill holes showed that it went deeper. The main stope, perhaps the largest in any mercury mine in North America, measures 360 feet long by 164 feet wide and 130 feet high. The ore was milled in a flotation plant at the mine, and the concentrates were shipped to another plant in which both the mercury and the antimony were recovered.

Huahuaxtla district.—The Huahuaxtla deposit, about 30 miles northwest of Huitzucó, was discovered in 1923. From 1941 through 1944 it has produced about 150 flasks of mercury a month. Although metacinnabar appears to be the chief ore mineral, about an equal quantity of inconspicuous, fine-grained cinnabar is present. Some carbonate, iron oxide, and a little gypsum accompany the ore.

The ore occurs in a gouge zone about 30 feet thick along a large fault which dips about 40° SW. and can be traced for several miles. Limestone forms the footwall and shale the hanging wall of the fault. The surface of the limestone in the footwall is characterized by parallel ridges 3 to 15 feet high, about 30 feet across, and 30 to 100 feet apart, that extend diagonally down the footwall surface in a westerly direction. The fault gouge consists of scattered limestone blocks in ground up shale, the blocks being largest and most abundant near the footwall.

The ore occurs in the fault gouge, and to a lesser extent in the fractured limestone adjacent to the fault. The largest ore shoots occur on the down-dip sides of the limestone ridges where the breccia is thickest, and therefore lie parallel to the ridges.

Nuevo Mercurio district.—The Nuevo Mercurio district was discovered in the desert country of northern Zacatecas, in central Mexico, in 1940. It is the most productive mercury district in Mexico, and one of the most productive in the Western Hemisphere. The monthly production has averaged 600 flasks or more, and at times has exceeded 1,000 flasks.

The Nuevo Mercurio district is in a small group of low limestone hills in a wide expanse of desert sand-flats. All water has to be brought 40 miles by rail and 15

miles by truck. The limestones and interbedded shales have been folded into many anticlines and synclines which trend N. 70° E. and are about 150 feet across. Some of the anticlines are broken by thrust faults. After the folding, two sets of approximately vertical fractures formed along which there was only small displacement. One set strikes about N. 30° W., the other about N. 10° E.

During mineralization much carbonate was deposited, and some gypsum was formed; cinnabar was deposited along many of the N. 30° W. fractures, and along thrusts following anticlinal axes. The largest and richest ore shoots were formed at the intersections of the N. 30° W. fractures with the thrusts along anticlinal axes. No ore has been found in the N. 10° E. fractures, although they contain abundant carbonate and unbroken anticlines are generally barren. Some post-ore faulting has occurred.

At Nuevo Mercurio there are 16 principal mines, about 50 smaller mines, and around 200 prospects. At one time over 900 retort tubes were in operation, but these were replaced during late 1942 and early 1943 by four 40-ton Herreschoff furnaces. Shortly afterward a 100-ton Herreschoff furnace and half a dozen 10-ton units of a newly developed furnace, called the Manfrino furnace, were added.

Cuarenta district.—The Cuarenta mercury district, discovered in 1932, is in the semi-arid mountain region of northern Durango, in central Mexico. Peak production of around 300 flasks a month was attained from 1940 to 1943. The district had produced a total of about 15,000 flasks before mining stopped in August 1943.

The oldest rock in the district is a granite that was injected, along joints, by diabase dikes and then truncated by erosion. Limestone conglomerates were deposited on the granite and later buried under a thick series of rhyolite tuffs and flows. After some minor silicification, the rocks were faulted and tilted, and cinnabar-depositing solutions rose along the faults. Where diverted and retarded by impermeable diabase dikes, faults, and silicified zones, the solutions deposited small, tabular cinnabar ore bodies, particularly near the granite—conglomerate contact. The largest ore shoots were formed at the intersections of two impermeable structural features, especially along the footwalls of the diabase dikes at their junction with the base of the conglomerate. In contrast, the few ore shoots that were localized by a single impermeable feature are small and low in grade. The ore is associated with chaledonic silica, iron oxide, and soft clay-like material.

Sain Alto district.—The Sain Alto district in western Zacatecas has produced about 200 flasks a month in recent years. The district is characterized by a highly deformed series of lower Upper Cretaceous sandstones and interbedded shales which are exposed in a piedmont area of about 40 square miles that is nearly surrounded by rhyolite mountains. The rocks are broken by numerous thrust faults and at least five sets of normal faults, most of them pre-ore. The cinnabar deposits are of two types: (1) Small deposits in the rhyolite in the mountains, and (2) desposits in the sedimentary rocks.

The cinnabar desposits in the rhyolite are widely scattered along great shear zones, some of which can be traced for miles. They are accompanied by extreme silicification and abundant iron oxide. The cinnabar is intimately mixed with a finely disseminated yellow mineral, probably a mercury chloride, that turns black in a few moments on exposure to the sun. The ore tends to occur in small rich pockets which are unattractive to large operators but which may be profitable to the local "gambusinos."

Ore has been found in the sedimentary rocks at only one place, but the principal mine there, which is 410 feet deep and still in good ore, yields more mercury than all the other mines in the district. The rocks have been broken by many faults, including numerous bedding-plane faults, accompanied by extensive drag-folding. The cinnabar occurs both disseminated in the sandstone and accompanied by carbonate in joints more or less perpendicular to the bedding. The ore-bearing zone as a whole cuts across the rocks without regard for their structure, and appears to be well defined, so that mining at deeper levels can be planned systematically. The distribution of the ore shoots within this zone, however, shows a delicate response to local structure and relative permeability of the sandstone.

Canoas district.—Cinnabar was discovered in the Canoas district, in the southeast corner of Zacatecas, in 1878. During the past few years the production has fluctuated widely but has been of the general order of 200 flasks a month. Here, a latite covered by about six feet of volcanic glass was raised into a dome which was broken at the top by several intersecting fracture zones. Cinnabar was deposited along these fractures, and the wall rocks were extensively altered. Intense silicification accompanied the mineralization and was followed by some carbonate

alteration of the wall rocks. After the mineralization the region was inundated by tremendous flows of rhyolite, that flowed against and around the pre-existing latite dome, perhaps barely overtopping it.

New Zealand.—The mercury mines of Puhipuhi are reported to be able now to supply the greater part of the requirements of Australia and New Zealand.⁹ The deposits were known and worked 20 years ago, but operations were suspended when exploratory work failed to disclose an extension of the ore body. The present expanded production began in 1941. Production is by open-cut methods, and the article describes the open cut as the deepest in New Zealand.

Spain.—The variation in 1944 production data for Spain makes it desirable to withhold figures until one or another total is confirmed. Reports indicate that 47,800 flasks were produced in 1943, compared with 72,300 flasks in 1942. Although Spain is reported to have supplied substantial amounts of mercury to Germany during World War II, and likewise to have sold substantial amounts to the Allies, stocks available for sale at the end of 1944 were reported to total 120,700 flasks, most of which was held by the Almaden operators. Owing to the large inventories, the Almaden mine was operating far below capacity at the end of the year, and it was the only productive mine in Spain. Almaden mine, of course, dominates the mercury output of Spain to such an extent that its output is always roughly indicative of the country's total. Rumors state that the mercury cartel, Mercurio Europeo, both is and is not in operation at the present time. It is rather difficult to see how it can be operating with Italian sales subject to rigid controls by the Allied Control Commission and with Spanish metal being offered in the New York market early in 1945 at prices far below the most recent cartel quotation of \$250 a flask.

Union of South Africa.—The expectation that the Monarch Kop mine, in the Murchison Range, might be able to supply not only home needs but an exportable surplus as well was realized recently. Production was reported at about 100 flasks a month in 1944. This property was brought into production under the high prices of the war, and its competitive position at postwar price levels is unknown.

GENERAL SUMMARY

Tin's unique position among the wartime strategic and critical metals was accentuated during 1944. Whereas the supply-requirements relationships for most metals eased after Allied control of sea lanes broadened and outputs of many war goods passed their peaks, needs for tin, already the most desperate among metals, grew despite painstaking efforts of the War Production Board to limit drafts on reserve stocks. The capitulation of Germany in May 1945 and the coincident end of the European phase of the World War, if anything, put additional demands on the dwindling stocks, with little relief to be expected much before the end of 1946.

Consumption of primary tin in 1944 rose 28 percent above the 10-year low of 46,253 long tons set in 1943, owing mostly to greater tin-plate output and the continued heavy requirements for bronze and bearing alloys. Imports of metal and tin concentrates were 49,842 tons (tin content) or about one-third greater than in 1943, but the gap between supply and consumption widened, notwithstanding diversion of part of the British share of Bolivian concentrates to the United States. The tin content thereof, 7,504 long tons, was almost identical with the increase in receipts from Bolivia, which reached a total 28,584 tons in 1944. The tin content of ore and concentrate deliveries from the Belgian Congo was about 85 percent greater in 1944 than in the preceding year, and Congo pig-tin arrivals fell off about one-eighth to approximately 10,000 tons; the net result was a gain in tin supply from the Congo of approximately 11 percent or 1,900 tons. About 3,300 tons of tin that had been flown from China to India was also received. Tin plate and terneplate, as usual, were the major export items and were about 10 percent higher than in 1943 but still nearly 25 percent less than the record of 593,776 tons in 1942.

¹ Subject to revision.² Including tin content of ores used direct to make alloys.³ Figures for 1940-41 cover foreign only; domestic not separately recorded.⁴ Ceiling price, 52 cents.

Year-end stocks, in terms of tin, were 100,297 tons, distributed as follows: As pig tin, industry 19,325, Government 39,870; and in ores and concentrates awaiting treatment, 41,102 tons. Although this represents about 1½ years supply at the 1944 rate of use, only two-thirds or about 12 months supply was available as metal. The Longhorn smelter turned out over 30,000 tons in 1944 and in the forepart of 1945 was producing at a 40,000-ton rate. If that rate can be maintained and if foreign metal supply is no less than in 1944, substantial inroads on the pig-tin stocks nevertheless may be expected in 1945, especially if the use of tin is permitted in industrial reconversion during that year. In view of the needs for European rehabilitation, the indicated decline in production available to the Allies, and probable shrinkage in British stocks, the United Nations supply-demand position also probably will deteriorate in 1945.

The sales prices for Straits tin or equivalent grades were held at 52 cents a pound, unchanged from 1942 and 1943. The prices for the Government's Longhorn brands were unchanged from those set in 1942. The British price of £300 a long ton for standard tin delivered buyer's plant was effective January 1, 1944, and was not changed during the year.

POSTWAR OUTLOOK

In the chapter of this series in Minerals Yearbook, 1943, the future primary metal consumption in the United States was forecast at about the prewar level of 60,000 to 65,000 long tons annually, except for a short period when wartime-accumulated wants were being met from the first ample postwar supplies. World consumption also was expected to return to the late peacetime figure of 150,000 tons.¹

Estimates of world production from a year to 18 months after the reoccupation of Malaya, Netherlands East Indies, and Thailand and Burma have been given as 120,000 and 184,000 long tons.

Although research and development were strongly supported during the year, no substantial new use was reported. Among the more promising developments was the proposed use of speculum (about 45 percent tin and 55 percent copper) as a competitor of chrome and

¹ Tin, official bulletin of the Tin Producers' Association, in the May 1945 issue, p. 10, however, estimates "the world demand for tin will not be less than 250,000 tons a year as soon as the immediate postwar needs have been met."

nickel for plating. During the war period no substitute for tin has been reported that gives promise of large displacement of tin in post-war years.

The postwar status of the Government's Longhorn tin smelter has been the subject of considerable discussion. The principal arguments advanced for the continued existence of the smelter are: Strategic importance, as a segment of State Department (Good Neighbor) policy, and for recovery of public investment. On the other hand it has been said these arguments are not wholly valid. Military security may be secured most simply by stock-piling metal, a method already adopted in the United States. If it should again be requisite to construct a plant, it has been demonstrated that it could be accomplished in a matter of months, and the technique of ore reduction need not be lost if the smelter ceases operation. Under the concept of Inter-American mutual support it is expected that Bolivia would continue to furnish the part of its production that can be considered available for open market sale. To assure its flow to the United States would imply the payment of a premium above free market price. Since this portion is inferior in grade and highly refractory the total cost of the tin produced therefrom would be much higher than that procurable elsewhere. No matter how the difference is covered it would be a levy on the taxpayer or consumer. (See section on International Tin Control Scheme.) The investment in the Longhorn smelter is approximately \$7,000,000. Its assured operating life will exceed 5 years; usual accounting procedure would have amortized a substantial part of the investment had the smelter been a private venture instead of an emergency undertaking, the total cost of which can be considered properly a war expense. Even if salvage value is neglected, the added cost per pound of product for 5-year amortization would be only about 2 cents a pound on the tin produced.

For 2 or 3 years longer, or until Far Eastern smelters resume production, operation of the Texas City reduction works is reasonably certain. Thereafter, in the absence of political control of ore sources by the United States, the future is unpredictable.

GOVERNMENT TIN PURCHASES

During 1944, 15,732 long tons of refined tin (13,850 in 1943) and 84,318 tons (gross weight) of ore and concentrates (55,000 in 1943) were purchased for Government account. Of the total quantity of ore and concentrates, 86 percent was acquired from Bolivia, 13 percent from Belgian Congo, and the remainder from French Cameroons and Mexico. The Bolivian ore was obtained under the 5-year contract with Bolivian producers that expires June 30, 1945; the portion from the Patiño group was received under a contract with Wm. Harvey & Co.

Two-thirds of the metallic tin acquired was from the Belgian Congo and the remainder from China. About 1,900 tons was stored in foreign ports or was afloat at the end of the year. Some Chinese tin was diverted to other destinations after being flown to India, and some was lost by enemy action.

Negotiations for a modification of the 5-year ore-buying contract more favorable to Bolivian producers continued during the year. On March 3, 1945, the Foreign Economic Administration announced that

the price to be paid for Bolivian tin during the remaining life of the basic tin agreement between Bolivia and the United States will be increased from 60 cents to 63½ cents. In addition thereto, the seller is to receive a bonus of 1½ cents a pound on the payable tin after unit deductions, "as an inducement to the seller to increase production." Thus, the effective increase is not 3½ but 5 cents a pound.² The price of 63½ cents is to be effective from December 19, 1944, to June 30, 1945, the date of expiration of the basic agreement. Inasmuch as the amendment had been under discussion since early 1944, it also provided for a retroactive increase of 2 cents a pound from July 1, 1944, to December 18, 1944. Provision is made for a new schedule of smelter charges designed to lend encouragement to the production of higher-grade ore and concentrates. The price increase also considered increases in wages and other production costs. Bolivia agreed to cooperate to keep production at the highest possible levels. The amendment contains a labor clause under which the producers agree to maintain standards of health and working conditions. In discussions with the Bolivian authorities in connection with the purchase of tin concentrates, the State Department was reported to have let it be known that it is not interested in extending government-to-government commodity contracts, and private business is expected to resume buying strategic materials when the war is over. An agreement was also reached to divert part of Patiño's shipments to the United States in 1945.

CONSERVATION

In the face of heavy drafts on stocks tin saving remained a matter of prime necessity. Only minor modifications of conservation or limitation orders were made in 1944. The general object was to permit manufacture or use of goods having superior properties or more closely adhering to industrial practices without increasing tin consumption.

Early in 1945 efforts were made to revive the lagging tin-can salvage campaign. Other secondary sources were drying up as a result of conservation measures first instituted in 1941, with reduction in tin plate coating-weight from the 1.5 pound per base box standard to 1.35 and the substitution of terneplate and black plate where feasible. (See sections on Secondary Production and Consumption by Uses.)

Electrolytic-tin-plate output of about 645,000 short tons was 95 percent greater than in 1943 and represented 30 percent of capacity. It amounted to 36 percent of standard coke-tin-plate tonnage, nearly twice the 1943 and 10 times the 1942 ratios. The average tin weight was 11.82 pounds per short ton compared with 26.24 pounds for standard cokes. The large share of tin plate used for military supplies precluded the full application of the thinly coated electrodeposited plate. Nevertheless, its use represented a saving of well over 4,000 long tons of tin. A material additional saving will arise when 0.75-pound plate is used for packing milk, announced to become effective in the third and fourth quarters of 1945. Although large-scale test results are not yet available, a new surface treatment for cans announced late in 1944 has distinct promise of promoting the use of

² The text of the amended Bolivian tin contract was published in *American Metal Market*, vol. 52, No. 52, Mar. 17, 1945, p. 5.

electrotinned plate. An alkaline detergent combined with a corrosion inhibitor is employed to film-packed cans, and the process is readily adaptable to cannery production lines. The film makes the exterior more resistant to rusting, a common cause of failure under humid conditions, than untreated hot-dipped plate. It has been found that some thin electrolytic plate test pieces show better corrosion resistance than others. Investigations were under way to discover the cause. If this fortuitous occurrence can be commercially repeated, the use of this class of tin plate for sanitary cans will be greatly enhanced.

In other use fields incomplete data render precise evaluation of conservation measures difficult. On a small sample, figures furnished the Bureau of Mines indicate that the average tin content of bronze and brass was approximately 5 percent in 1943 and 1944 and roughly 4 percent in 1939. For a group of manufacturers who used more than half the tin (primary plus secondary) contained in solders the approximate tin content was slightly less than in 1943 at 27 percent. In babbitt metal the total output was 30 percent greater, but the indicated tin content dropped sharply to about 14 percent, thus approaching the limit set up in Conservation Order M-43.

INVESTIGATIONS OF DOMESTIC TIN DEPOSITS

The Bureau of Mines and Geological Survey in 1944 continued investigations of tin occurrences as a part of their strategic mineral programs. Field examinations and explorations were made in the Gorman district of Kern County and the Cina district of San Bernardino, Calif.; in the Franklin Mountains near El Paso, Tex.; and in the Black Hills of South Dakota. In Alaska the most extensive work was carried out in the western part of the Seward Peninsula. Placer deposits in that area near Tin City furnished most (nearly 500 tons) of the domestic tin output in the last decade. Both placer and lode deposits have been examined.

The Geological Survey in a press release dated February 26, 1945, covering the work of the two agencies in Alaska in 1944 reported the discovery of tin-bearing veins in the Cape Mountain area. The deposits are of a type that could have been the source of large pieces of tin ore found in nearby stream gravels. Although the ore bodies are not large they make the outlook for additional discoveries more favorable than it was thought to be in the past. In the Lost River area tin has been found in veins, dikes, and mineralized zones cutting the limestone near the dikes. The dikes carry little tin at depth, but drill cores indicated a fair tin content in the veins and mineralized areas, as well as in the upper portion of a granite mass that lies a few hundred feet below the surface. The extent of the mineralized granite was being determined in 1944.

The report of the Director of the Bureau of Mines summarizing the results of work in the fiscal year ended June 30, 1944, stated that six deposits in Alaska and three in continental United States had been explored. In three of them a recoverable reserve of 3,450 tons of tin was indicated.

DOMESTIC PRODUCTION

MINE OUTPUT

Domestic production continued to be insignificant. The Metals Reserve Company discontinued the purchase of domestic and Alaska tin ores at its various depots December 31, 1944. Thereafter, terms of sale were to be furnished prospective sellers of tin ore upon application direct to Metals Reserve Company, Washington 25, D. C. The purchase depots acquired tin concentrates containing about 4 tons of tin in 1944, some of which had been mined in previous years.

² Included in total.

SMELTER OUTPUT

Domestic tin smelters produced 30,884 long tons of tin in 1944 or nearly double the peak output in the first World War period. Most of it came from the Government-owned Longhorn smelter, and the remainder appeared largely in the form of alloys.

The 50-percent rise in pig-tin output at Texas City resulted from improved operating procedures in smelting and ore dressing, notably in lengthened furnace campaigns.

The principal plant improvements were the installation of mechanical samplers and conveyors for ore bedding in the ore-storage building and the addition of a thickener, filters, and a flotation unit for oxide flotation in the ore-dressing section. Near the end of the year two of the nine reverberatories were being converted to a single unit with a waste-heat boiler.

Satisfactory results were achieved with charges containing approximately 90 percent complex Bolivian ores of about 40 percent tin content (including the better-grade Patiño ores)—the first large-scale operation on ores of about 65 percent of the tin content of those usually smelted in England and about 55 percent of those smelted in Holland, Malaya, and the Netherlands East Indies. Although five grades of pig tin have been produced, recent practice has been to make only Three Star or Grade A (99.80 percent Sn and over) and no star or Grade F (less than 99 percent Sn). More than 80 percent of the output is of first quality. Representative analyses of the several grades are given in the following table. A summary of tin smelting practice in the United States, United Kingdom, and Malaya was published.³

³ Mantell, C. L., Recent Progress in Tin Smelting and Metallurgy: Trans. Am. Inst. Min. and Met. Eng., vol. 159, 1944, pp. 530-547.

New pyrometallurgical processes for the recovery of tin from tin sulfide concentrates or tin concentrates relatively high in sulfur and iron or from hardhead have been developed.⁴

Longhorn smelter shipments were 37,112 long tons, of which 32,856 tons were Three Star and most of the remainder Grade F and One Star. Industrial users received about 25,100 tons, and the remainder was distributed to Government warehouses in Brooklyn, Chicago, St. Louis, and Texas City.

Only two privately owned smelters were in operation in 1944—the American Smelting & Refining Co. and the Nassau Smelting & Refining Co. Most of the tin recovered was as alloys, principally solder.

SECONDARY TIN

The total recovery of secondary tin decreased 14 percent in 1944 compared with 1943 to the lowest point since 1939—as scrap supplies dwindled. Decline in quality was also in evidence, especially in white metals, tin-plate clippings, and old containers. Detinning-plant output was the lowest since 1935 and 11 percent below that of 1943. Although the quantity of clean tin-plate clippings treated increased about 10 percent it was more than offset by the decrease in supply of old tin cans. Recovery was influenced further by a drop in tin content that was especially marked in used containers—about 15 percent—as a consequence of the growth in use of electrolytic tin plate and the limitation on weight of hot-dipped coatings.

The Government-owned detinning plant at Birmingham, Ala., was in operation during the year. The wartime auxiliary operations of the National Lead Co. and the Tin Salvage Institute as agents for Metals Reserve Company ceased by the end of the year. The first named recovered 4.5 long tons of tin from old type metal in sodium stannate that was converted to metal at another plant, and the second had a production of about 485 tons of tin in the form of alloys. The totals for the campaigns were respectively 44.5 tons and 913 tons, virtually all as tin alloys.

Collection of used tin cans, part of which are employed for precipitating copper from mine waters, decreased nearly 12 percent or about 21,500 long tons compared with the 1943 returns, and the quantity of tin recovered dropped about one-quarter. The War Production Board amended Conservation Order M-325 further to direct delivery of old cans to detinners. In February 1945 the order again was amended, setting up country-wide mandatory provisions for collection, segregation, and disposal of used cans offered to refuse collectors: To insure continued collections the Metals Reserve Company in December 1944 agreed "to pay subsidies to detinners up to 13 cents a pound for all tin produced to compensate them for a loss in revenue that followed the drop in scrap steel price that took place late in the year." Further details on secondary tin will be found in the chapter on Secondary Metals—Nonferrous.

CONSUMPTION

APPARENT CONSUMPTION

In 1944 the apparent consumption of primary tin was 37 percent higher than in 1943. Apparent consumption is computed by adding domestic smelter production to net imports. It does not take into account fluctuations in consumer, dealer, and Government stocks; consequently, it may deviate widely from actual consumption as measured in finished products, which in 1944 was 36 percent above the calculated figure. Nevertheless, the apparent consumption series is useful as an indicator of long-term trend. The data for 1939-44 are given in the subjoined table:

Apparent consumption of tin, 1939-44, in long tons¹

1939-----	67, 987	1942-----	42, 512
1940-----	123, 537	1943-----	31, 749
1941-----	141, 618	1944-----	43, 379

¹ The series 1910-38 was published in Minerals Yearbook, 1939, p. 680. Exports of domestic tin were not included in 1931-41 inclusive. They are included in the figures for 1942-44 and are 244, 398, and 405, respectively.

CONSUMPTION BY USES

Actual consumption of primary and secondary tin as reported to the Bureau of Mines is shown in the following tables. Total consumption rose one-eighth above the 1943 low, whereas that of virgin metal jumped about more than a quarter in consequence of the growing scarcity of scrap, principally tin-bronzes, and bearing alloys, as well as degradation, and greater product requirements than in the preceding year. The product figures actually understate the use of new metal, inasmuch as tin contained in process scrap or other waste is considered as secondary.

The continued concentration of production on war materials brought no wide departure from the relative distribution of tin by primary uses reported in the 1943 review. Tin plate held first place as a user of virgin tin and took 42 percent of the consumption. The increase of 3,300 tons or 15 percent compared with 1943 was the net result of a 21-percent gain in the output of tin plate, of which 26 percent was electrotinned. In respect to solder, the prewar relationship between primary and secondary tin was resumed. Total tin use increased only 7 percent, but that of secondary fell 34 percent, whereas that of pig tin jumped 65 percent, a striking evidence of the effect of conservation through wide application of low-tin or virtually tin-free solders. Although the production of white-base bearing alloys rose nearly 20 percent to 61,464,334 pounds, according to the United States Department of Commerce the consumption of tin in babbitt was only 11 percent greater than in 1943 because of the permissible tin limit. The effect of earlier degradation coupled with some scarcity of scrap brought about abrupt reversal of the 1943 primary: secondary ratio of 3:4 to 2:1 in 1944. The attainment of a new peak in the shipbuilding program was principally responsible for an 11-percent increase in total tin consumption for bronze and brass; almost all of it was virgin metal and accounted for nearly one-quarter of its use. Bronze and brass thus remained in second position as primary tin consumers for the second year and in total tin used exceeded tin plate by essentially the same margin as in 1943. In other fields of use, roughly 20 percent or 950 tons more virgin tin was consumed than in the preceding year. The planned industry reconversion and military matériel cut-backs to follow the cessation of war in the European theater probably will bring about reversion to the peacetime relative positions in the four major use areas. However, the quantitative distribution will be modified, owing to the scarcity of virgin tin.

¹ Includes 9 tons of primary and 2 of secondary for britannilware and 2 tons of primary for pewter.

² Includes 6 tons of secondary for pewter.

FOREIGN TRADE ⁵

Imports of tin concentrates and exports of tin plate were the principal elements of the foreign trade in tin of the United States during 1944. Pig tin ceased to dominate the import field in 1943, as this country was denied access to former Asiatic sources. There was slight improvement in the situation with the resumption in April of imports of Chinese tin, which had been flown out and shipped from India. Consequently imports of metallic tin increased (11 percent), despite a 13-percent decline in receipts from the Belgian Congo, our main source of foreign pig tin at present.

The Longhorn smelter, Texas City, Tex., was the destination of virtually all tin concentrates imported in 1944. The tin content of the material imported was 36,504 tons (21,857 in 1943), establishing a new record by exceeding the 1942 imports of 28,933 tons, the previous high. Bolivia continued to be the principal source, supplying 28,544 tons compared with 17,351 in 1943. The increase was due to acquisition of a large tonnage of concentrates produced by the Patiño group. Imports from other sources included: Belgian Congo, 7,549 tons (4,094 in 1943); French Africa, 177 (291 in 1943); Peru, 146; Mexico, 46 (121 in 1943); and Argentina, 42.

Exports of tin plate, terneplate, and taggers tin increased 10 percent in 1944. For the most part they went to Latin-American countries (31 percent) and Australia and New Zealand (31 percent), which increased 9 and 5 percent, respectively. Exports to Russia (accounting for 10 percent of the total) increased 53 percent; those to India (8 percent), 52 percent; and those to African destinations (8 percent),

⁵ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

9 percent. Exports to Canada (8 percent) declined 4 percent and those to miscellaneous countries (4 percent), (principally Egypt), 19 percent.

¹ United Kingdom of Great Britain and Northern Ireland.**PRICES**

The price of tin remained stabilized in the United States at established Government maximums or ceilings throughout 1944. Under Maximum Price Regulation 17 (Tin) issued by the Office of Price Administration, September 16 (effective September 22, 1943), the maximum prices, by grades and brands, are as follows:

Grade A. 99.80% or higher, meeting specifications set forth in M. P. R. No. 17.....	52.00c.
Following brands of pig tin will be considered as qualifying as Grade A: Longhorn 3-Star, Chempur, Pyrmont, Straits Trading, O. T. Lempriere & Co., E. S. Coy (Penang), Billiton, Mellanear (Guar. 99.9%), Hawthorne Refined, Banka, Union Min. du H. Katanga, M and T No. 1, M and T Electrolytic Refined, Vulcan American Refined, Vulcan Electrolytic.	
Grade B. 99.80% or higher, not meeting specifications for Grade A, providing arsenic content does not exceed 0.05%.....	51.87½c.
Grade C. 99.65% to 99.79% and 99.80% or higher, not meeting specifications for Grade A or Grade B.....	51.62½c.
Grade D. 99.50% to 99.64% (includes Longhorn 2-Star).....	51.50c.
Grade E. 99.00% to 99.49% (includes Longhorn 1-Star).....	51.12½c.
Grade F. Below 99% pure (for tin content) (includes Longhorn No-Star).....	51.00c.

On January 1, 1944, the London price was advanced £25 per ton to £300 for metal ranging between 99 and 99.75 percent tin content.

¹³ Based upon price indexes of U. S. Department of Labor.

According to The Metal Bulletin (London), issue of January 30, 1945:

There are no international prices of tin at the present time, for although the official selling prices in the United States and in the United Kingdom are roughly in line—tin-hungry neutrals and liberated countries would probably be prepared to pay almost anything for urgently needed supplies. It is known that prices upwards of £60 a ton more than the official selling price in this country (United Kingdom) have been paid for export business, and it is suggested that £400 could readily be obtained in some directions if it were possible to send the tin.

STOCKS

Total year-end stocks of primary tin plus tin content of the ore and concentrate supply in the United States in 1944 were 12 percent below 1943. The Government held 81 percent and private industry the remainder. The quantity (in terms of tin content) held by the Government was divided about equally between metallic tin and in ores and concentrates. Government stocks of pig tin were depleted 26 percent and industrial stocks 17 percent. Virtually all the industrial stocks were in the form of metal; only a very small quantity was in ores awaiting treatment at privately owned plants. The total quantity on hand was equivalent to about 1.6 years supply at the rate of consumption in 1944. However, if consumption continues at the 1944 level and the flow of supplies are likewise maintained, the stock pile would be sufficient for about 7 years.

The Bureau of Mines canvassed tin consumers to determine stocks and use during 1944. According to these reports, the consuming industry had 17,337 tons of primary pig tin at plants at the end of 1944, including 8,442 tons held by tin-plate manufacturers. The industry also had 1,941 tons of primary tin in transit or warehoused in addition to 49 tons of secondary pig tin on hand at the end of the year.

⁵ Includes 2,700 tons in transit in the United States and at other warehouses not contained in figures above for "at landings" and "in licensed warehouses."

⁶ Includes 78 tons in transit and 84 tons held by jobbers.

⁷ Includes 316 tons in transit and at other warehouses and 50 tons held by jobbers.

⁸ Includes 1,941 tons in transit and at other warehouses and 47 tons held by jobbers.

⁹ Exclusive of Government purchases delivered for stock-piling or at Texas City smelter;

WORLD ASPECTS OF TIN INDUSTRY

WORLD MINE PRODUCTION

Official information on mine production in tin-producing countries is still meager. However, it appears probable that the total output was even below the estimated total for 1943 and insufficient to balance consumption. Allied military successes in the Far East contributed thereto, and it seems likely that the decline will continue until the Japanese have been driven out of tin-producing regions in the Pacific area. There is growing evidence that in other parts of the world the higher grade and more accessible portions of deposits have been mined and that development has not paced extraction.

WORLD SMELTER PRODUCTION

Output of the world's operating smelters, principally concentrated in 1944 in the Belgian Congo, United Kingdom, and United States, was keyed to the new ore supply, and hence world tin-smelter output probably reached a new low point for over 2 decades. For the first time on record the United States attained first place in the production of refined tin.

The modern 30,000-ton smelter of the N. V. Nederlandsche Metallurgische Bedrijven, a subsidiary of the Billiton Company, at Arnhem, Holland, was damaged extensively during the European campaigns. No information has been disclosed concerning its possible reconstruction. It has been assumed generally that Malayan and Netherlands East Indies smelters also have been or will have been destroyed before the war terminates.

INTERNATIONAL TIN CONTROL SCHEME

Extension of the fourth control agreement that expires December 31, 1946, has become the subject of much discussion abroad and in the United States. The arguments are of more than usual interest because of the entrance of new and important factors: The attitude of the American Government toward cartels; the future of large-scale domestic tin smelting; and the anticipated recovery of the Malaysian tin areas more or less coincidentally with termination of the present agreement.

Proponents of control measures advance in general arguments set forth in the past and more recently by the Tin Producers' Association (an operators' group). Some elements, nevertheless, recognize that, as now constituted, the International Tin Committee (ITC) (essentially a group representing the tin interests of the major tin-producing countries) would not be adequate to fulfill the postwar requirements of the main consuming and producing countries. To meet this difficulty it has been suggested that consuming (or smelting) countries might be given an active voice in ITC deliberations and that the United States Government might not be averse to such participation. Reference was made in the chapter of this series in Minerals Yearbook, 1943, to a historical review of the International Tin Control and Buffer Stocks as presented by the Tin Producers' Association.⁶ According to the association, the main functions of the ITC were "to prevent excessive accumulations of stocks and to provide an ample supply of

⁶ Also appeared in 1944 as pamphlet under above title.

tin at a reasonable price." Industrial stability is obtained only when there is close equilibrium between supply and demand. In the instance of tin, this was to be gained by control of exports from the countries signatory to the International Control Scheme operated by ITC, which would insure a balance over relatively long periods. Tin demand, however, fluctuates sharply and rapidly and independent of price. It thus became necessary to develop an auxiliary regulatory device—a surge tank—which was accomplished in the form of the so-called buffer stocks. Through the application of this two-part system, it was claimed, both producers and consumers benefitted, because prices were held at reasonable and stable levels compared with those of the preceding uncontrolled period. The war demonstrated further the advantage of a control that brought about maintenance of productive capacity through the depression period.

Opponents of restriction schemes state, among other things, that the control operated to hold prices at such a height that operations were remunerative to marginal and uneconomic producers. Much redundant capacity thereby was kept in being, and consumers suffered through excessive prices. The proposed solution to these and other attendant ills is a return to free competition. In a well-documented review of the operations of the ITC, A. J. Knorr⁷ comes to essentially the same conclusion. He avers that the committee failed to control excessive price gyrations although successful in maintaining very high prices that were profitable to the entire producing industry, including an obsolescent section; and that the total cost of control was borne by the ultimate consumer. Inasmuch as the control was political, that is, governed by producers and producing countries, and though it was susceptible to some economic motivation—control of production was not complete nor was consumption regulated—it was undesirable and ineffective with reference to the greatest social good. A tight commodity control in practice is likely to develop evils worse than those of an unregulated market.

A definite solution to the problem is not offered, but in view of the well-organized and strongly backed efforts to extend control some proposals are tendered. It is taken for granted that the United States, as the major consumer, will have considerable influence in the matter. In the transition period, until rehabilitation in Far Eastern tin fields has been completed, the wartime controls exercised by the United Nations should not be relaxed. This would insure equitable distribution of supplies and prevent runaway prices. Over-expansion of productive facilities could be discouraged or limited by Government and producer-group cooperation. Intensive research—economic and technical—should be continued to afford a sound groundwork for decision as to the desirability of longer-term control. To attain production-consumption equilibrium lengthy control would be necessary to ameliorate the losses to owners of superfluous capacity. Bolivia presents a special and difficult case. It is the highest-cost producer; Bolivian economy depends almost completely on tin production. Only a radical solution is possible. In substance the burden must mostly fall on the United States, possibly a share being borne by the United Kingdom. The author does not agree with the Tin Producers' Association statement that buffer stocks can be made an adjunct of a

⁷ Knorr, A. J., *Tin Under Control*: Food Research Institute, Stanford University, Calif., January 1945, 314 pp.

restriction scheme because no such scheme has been devised to concentrate and maintain production only in economic units. Alone they can, however, moderate short-term excessive fluctuations in price from the secular trend if intelligently and impartially directed. It is obvious that they must be large in size because of supply rigidity and consumer tendency to maintain low stocks when visible supplies are large. Such stocks might be considered, at least in part, as strategic reserves.

On the whole, Dr. Knorr is inclined to believe that vested interests will not adopt the suggested plans, consequently a free tin market would be preferable to that heretofore maintained by ITC.

REVIEW BY COUNTRIES

Australia.—Tin production in Australia in 1944 was probably the lowest recorded for any year during the past decade. Tin stocks were depleted so that it became necessary to divert some Chinese tin to meet essential requirements in Australia and New Zealand. Mining was handicapped by labor shortages and was adversely affected by a drought of unprecedented severity. Operations by the Tableland Tin Dredging, N. L., Mount Garnet, Queensland, now the leading tin producer in Australia, proceeded at a greatly increased rate during most of 1944. Output by Briseis Consolidated, N. L., in Tasmania, the second largest producer, was much lower, as the grade of ore decreased materially and manpower difficulties grew. Production of tin in Tasmania declined sharply during the year ended June 30, 1944, according to the annual report of the Minister for Mines. A Government subsidy of £A3,000 was granted for development work in the Renison Bell tin area in Tasmania. The Mount Bischoff mine controlled by Government was worked by leasers; operations were confined mainly to sections of the open-cut. The Minister of Supply offered to buy concentrates containing 70 percent tin or more from miners and prospectors at £A231 per ton. The Australian Council for Scientific and Industrial Research reported the development of a new flotation process for recovery of tin from lode-tin ores. The method was said to be applicable to both current and old tailings.

Belgian Congo.—Production of tin ore and concentrate declined 12 percent in 1944 from the record established in 1943. The remarkably rapid development of tin mining in the country is revealed by the fact that approximately two-thirds of the total recorded output was made during the period 1940–44. This was mainly owing to the insistence of the Belgian Government on maximum production as an aid to the Allied cause. The decline in output in 1944 resulted in part from transition to lower-grade ores, from drought conditions, and perhaps from some resumption of gold-mining operations.

The United States Government contracted for the purchase of all tin produced in the Belgian Congo during 1944, understanding that a part thereof would be made available to Belgium whenever that country was liberated. Metallic tin and tin in ore and concentrates imported by the United States from the Belgian Congo declined 11 percent in 1944. Metallic tin imported was 10,000 tons (11,550 in 1943) and 7,549 tons in ore and concentrates (4,094 in 1943).

Belgium.—The restoration of the port of Antwerp and its vicinity probably means early resumption of tin smelting by the Soc. Gén.

Métallurgique de Hoboken. The capacity of the plant was formerly rated at 10,000 tons of U. M. H. K. brand of tin annually which was produced mostly from tin ore mined in the Belgian Congo. Some pig tin and tin ore from the Belgian Congo may be diverted to Belgium from the Congo via the United States in 1945.

Bolivia.—Since the inception of the first International Tin Control Scheme in 1931 Bolivia exceeded its standard quota four times but on the average for the full period has failed to meet it by more than 7,000 long tons annually. Concentrates and ore exported contained 38,719 long tons of tin in 1944, a 4-percent decrease compared with 1943. However, with the exception of 1943 and 1941, the quantity was greater than in any year since the peak production of 46,341 tons in 1929. The United States was the destination of about 19,568 tons or 51 percent, and the remainder went to the United Kingdom. United States general imports in 1944 from Bolivia were 28,584 tons (including 7,504 tons from Patiño's 1943 production) and 12,377 tons (gross weight) were afloat destined to the United States at the end of the year. About half (10,000 tons) of the Patiño-group output in 1945 will be shipped to the United States in 1945. In general, the decrease in exports in 1944 was due to several adverse factors, including cessation of operations by several medium producers, labor troubles, and political unrest. Exports reached a very high level in September owing to delayed shipment of mill accumulations. The exports of the Patiño group, the principal producer, amounting to 49 percent of the total, declined 6 percent; those of the Hochschild group, 26 percent, declined 1 percent compared with 1943; and the medium and small mines, with 19 percent, declined 4 percent. Tin Placers Corp. suspended operation of its dragline and washing plant September 15 and is now reported to be bankrupt. Under a November 1942 contract the company delivered about 287 long tons (gross weight) of tin ore to the Metals Reserve Company.

After long-drawn-out negotiations a second amendment to the 5-year Bolivian-United States ore-purchase contract, expiring June 30, 1945, was signed on March 3, 1945. It provided principally for upward revision of price over that of the first amendment (60 cents a pound tin content f. o. b. South American ports) which for about 6½ months before the contract ends was 3½ cents plus a bonus of 1½ cents a pound. The small miners' group (mineros chicos) represented by the Banco Minero was favored by permission to ship a higher proportion of low-grade concentrate (below 35 percent payable tin to the 18-percent rejection point) than the other sellers without treatment penalty. In view of the probable delivery of an excess of low-grade material over that desirable for balanced operation at the Longhorn smelter, the U. S. Commercial Company has arranged to sell and ship in 1945 any excess to the Vulcan Detinning Co. at Seward, N. J.

No new mining taxes appear to have been levied by the Bolivian Government in 1944. Nevertheless it acted to increase the cost of mining by social and labor legislation, including additional pay for night work, increased employer contributions for compensation insurance, severance pay, wage payments for 12 holidays, and Christmas bonuses. After the amended contract was signed the valuation of ore and concentrates for export-tax purposes was raised to the contract price levels plus 1½ cents, the difference between f. o. b. and c. i. f.

prices. It was also decreed in April 1945 that 60 percent of the foreign exchange received for exports could be requisitioned for conversion to bolivianos, compared with 42 percent theretofore.

The new \$750,000 sink-and float-process plant that had been completed at Llallagua (Catavi) by the Patiño group late in December was expected to be in full and successful operation by March 1945. Its capacity is 5,500 tons per day, and it will be used for mine ore or tailings. The newly designed \$140,000 Sullivan tilting-deck tables installed at the Catavi and Centenario mills to treat very fine slimes that now are lost in the tailings were expected to be brought into full operation early in 1945. They are rated at 1,000 tons a day. The \$1,250,000 Tainton-process pilot plant of about 250 tons daily capacity at the Hochschild-operated Potosi properties was completed in October, and although trial runs have indicated that the metallurgical aspects of the plant are successful certain mechanical difficulties remain to be remedied.

The Bolivian Government has continued to contribute to the Tin Research and Development Council at London, doubling its previous contributions in 1944. The amount was reported to have exceeded £7,000.

British Malaya.—Authentic news regarding the tin mines and smelters of British Malaya has been entirely lacking during 1944. Dredging was formerly the principal means of tin-ore production. Resumption of production by dredging probably will be a slow process after the Japanese have been driven out; some Britishers have expressed the opinion that 5 to 10 years may elapse before the various enterprises can hope fully to reestablish their separate undertakings.

Mining ores by hydraulic sluicing, gravel pumping, hand panning, and other methods may provide an appreciable output of high-grade concentrates without much delay. These mining methods were formerly favored by individual Chinese miners, particularly gravel-pumping operations because of the small capital required and suitability for effectively mining small areas. The majority of the hydraulic mines (of which there were over 100) were small Chinese workings in the hill areas depending upon ditches for water supply. "Dulang washing" formerly contributed about 2 percent of the total output. As these several types of mining methods contributed almost 40 percent of Malaya's output in 1939 they may be expected to be able to supply up to 1,800 tons of tin per month soon after communications have been restored. Production from these sources was probably very small in 1944 because of resistance of Chinese to the invaders, shortage of food, oil, and other supplies and sabotage of Japanese-supported or enforced operations.

The Malayan Chamber of Mines has continued its efforts to impress upon the British Government the urgent need for prompt action on a definite plan for compensation of war-damage losses and for financial assistance in reequipping mines so that they may resume operations as soon as the Japanese have been driven out of the tin fields.

Burma.—The production of tin ore in Burma was not large in the past; in 1939 it contained about 8,500 tons of tin. No definite information on output has been disclosed since 1939, but prospects are now favorable for the resumption of tin mining. The Japanese overran the country in 1942, and by early 1945 rapid progress was being made by the Allied military forces in driving them out. Rangoon

had been recovered, and by May 1945 British forces were moving steadily down the road southeast of Toungoo toward the property of Mawchi Mines, Ltd., an important producer.

Canada.—Tin continued to be recovered as a byproduct in the treatment of the silver-lead-zinc ores of the Sullivan mine in British Columbia. Production was 231 tons in 1944 compared with 347 in 1943. The concentrate assays about 64.9 percent tin and 0.22 percent lead. Electrolytic refining is employed because of the difficulty of otherwise controlling the lead content in refined metal. An average assay of the pig tin is: Sn 99.647, Pb 0.31, Bi 0.002, Cu 0.006, Fe 0.006, Co 0.004, Al 0.005, Mn 0.005, and Zn 0.005 percent. According to Warren and Thompson,⁸ there is a "tin belt" in Western Canada, and while attempts to find and produce tin so far have been unsuccessful, except for the byproduct tin from the Sullivan ore, there seems to be enough evidence on hand to indicate that commercial tin deposits may exist and that a thorough search for them is fully justified. Imports of pig tin, which have been greatly curtailed during the past 2 years, amounted to only 1,197 tons in 1944 and 1,175 in 1943. The iron and steel industry (for making tin plate) has been the principal consumer of pig tin. A modern strip mill for the production of sheets and tin plate is to be built by the Steel Co. of Canada, Ltd. The company already has completed a tin-plate plant and a 110-inch plate mill. These additions, with those of other producers of tin plate, probably will be adequate for all of the internal requirements of Canada after the war. Before the war Canada imported about 80,000 tons of tin plate annually, mostly from the United Kingdom and the United States.

China.—Mine production has dropped steadily for about 10 years and probably was less than 3,000 tons (tin content) in 1944. Labor, fuel, and mining supplies were already critically short when the Burma road was closed in 1942. Since then internal economic conditions have rapidly grown worse, and inflation is virtually uncontrolled. According to the Metal Bulletin (London) of August 8, 1944, the price of tin was the equivalent of C\$15,000 a ton or about C\$7 a pound. The daily press early in 1944 reported the exchange rate to be about C\$200 to the United States dollar. Under such circumstances and notwithstanding completion of the Ledo road link to India and re-opening of the Burma (Stilwell) road about the beginning of 1945, little expansion in tin mining is to be expected soon because of the necessary concentration on the movement of military supplies.

Smelter output was reported by the National Resources Commission to have been only 2,195 metric tons. The largest smelter, that at Kokiu in Yunnan Province, was said to have ceased operation. The PKMA plant at Papu in Kwangsi was probably inoperative because the Japanese were in control of Hunan, Kwangsi, and Kiangsi Provinces, the sources of its ore supplies.

The United States had acquired 7,650 tons of tin in China in 1944, and a large part was flown out to India. Part of that arriving in India was diverted to other destinations, some remained in storage, some was lost in transit, and some was lost to the Japanese when they captured the United States air base at Kweilin. Tin imports from China via Calcutta were 3,338 tons in 1944. In addition to exports

⁸ Warren, H. V., Thompson, R. M., Tin in Western Canada: Western Miner, vol. 17, No. 8, August 1944, pp. 40-46.

to the United States, 170 tons went to Russia in 1944 and 4,040 in 1943.

France.—It has been reported that 2,000 tons of tin have been included in the French emergency program of nonmilitary purchases. Before the war consumption of tin in France averaged 9,100 tons annually.

Germany.—Where tin was absolutely essential for the production of war machines Germany appears to have had enough, although there was some indication late in 1944 that the supply situation had become almost desperate. Tin-plate production virtually ceased, and the canning industry depended almost entirely on black, bonderized, or otherwise chemically treated plate. Germany continued to collect scrap, although on a much smaller scale than a year or two earlier, partly because supplies in occupied Europe were exhausted and also because retreating armies cannot recover battlefield scrap. However, a large stock of bells was found by Allied forces, and it is believed there remained at the end of the war sizable quantities of other alloys and tin scrap. Frantic efforts were being made by German agents in Portugal to get metallic tin to Germany in October.* Before the Portuguese Government banned tin exports, the Germans bought large consignments and obtained permission to export up to the middle of November. The liberation of France barred the overland route, and the Allied air blockade practically barred air transport.

Germany's prewar smelter-tin output was about 12,000 tons. The principal plants were the Berzelius Metallhütten at Duisburg-Wanheim, the tin-recovery plant of Th. Goldschmidt at Essen, Norddeutsche Affinerie at Hamburg and Tempelhof A. Meyer at Berlin. All these cities were heavily damaged by Allied air or ground attacks, and it appears probable that the plants were damaged likewise.

Japan.—Small quantities of tin have been produced in Japan for centuries. Average annual production steadily increased from 300 tons in 1915 to 2,100 tons in 1938. Consumption usually exceeded production, and before 1938 Japan imported most of its needs from the Straits Settlements. Imports increased almost 70 percent during the 5-year period ended with 1938 and probably exceeded actual needs, so that a large portion doubtless was accumulated for strategic purposes. Consumption during 1944 has been estimated at less than 15,000 tons, so that little of the potential tin-producing capacity of the Far East was needed for Japan's own demands. It is not believed that very large quantities of tin could have been shipped to Germany during 1944, although a small tonnage was reported as cargo aboard a U-boat that surrendered. The near extinction of the Japanese merchant marine by the end of 1944 ended exploitation of the rich Asiatic tin fields.

Mexico.—The output of tin in Mexico was 317 tons in 1944—a decline of 26 percent compared with 1943. The control of the tin placers believed to occur in Santiaguillo Lake (Guatimape) and San Bartolo Lake in the State of Durango was transferred to the Comision de Fomento Minero. These two areas comprise 585 and 79 square kilometers, respectively, and are close to the railroad that runs between Durango and Tepehuanes, 100 kilometers north of Durango. Plans by private mining organizations to operate dredges for recovering placer tin from the lakes have been rumored.

*Tin, Flying Tin to Germany: November 1944, p. 12.

Netherlands.—One of the largest and most modern tin smelters in the world before the war was at Arnhem. The smelter was built on a small scale in 1928 and expanded continuously in size up to 1938, when its annual capacity was reported to have been 30,000 tons of refined tin. The tin concentrates treated for the most part were from Netherlands East Indies and Bolivia. Operations were curtailed sharply in 1939 when the Allied blockade interrupted imports; the plant fell into German hands in May 1940. There was no news regarding operations during the German occupation, but it is now learned that the plant probably was destroyed before Arnhem was reoccupied by Allied forces. Until possible rebuilding or resumption of operations if supplies of concentrates are available it has been presumed they may be shipped to the Texas City tin smelter for treatment.

Netherlands East Indies.—The only possible source of tin produced in the Netherlands East Indies in 1944 would have been scant output of native laborers using primitive methods. On Billiton, Banka, and Singkep there were probably 25 bucket dredges of different sizes and capacities and 5 hydraulic dredges (on Billiton and Banka), which were probably destroyed or seriously damaged before the Japanese occupied the islands. At the time of the Japanese invasion about 60 open pits and 1 underground mine were working, in addition to small operations on deposits of limited size. The tin mines of Banka were owned and operated by the Government under the management division of the Government Bureau of Mines at Bandoeng, Java. On Billiton and Singkep the Billiton Maatschappij (Co.) operated the mines jointly with the Netherlands East Indies Government. The ores from Billiton and Singkep and a small part from Banka were formerly shipped to Arnhem, Netherlands. After the invasion of Holland the ore produced in Billiton and Singkep was sent either to Singapore or to the United States. Formerly only a small part of Banka's concentrate was shipped, as the greater portion was treated in local smelters at Pangkal Balem, Muntok, and Belinjo.¹⁰

Nigeria.—It is likely that in 1944 Nigerian production declined slightly from the 1943 level, despite inducements by the Government to maintain maximum output. Operations were affected adversely by labor shortages, unfavorable weather, inadequate development, and delay in obtaining machinery. The compulsory labor program of recruiting from all parts of Nigeria proved unsatisfactory, and by the spring of 1944 all conscript labor had returned home.

The Ministry of Supply has provided for compensation for the uneconomical working of properties in order to obtain a maximum supply of tin. The Nigerian Mining Association accepted an offer from the Ministry of Supply to purchase all tin concentrates of 70-percent metal or better from all producers not already under direct contracts. The terms of purchase are retroactive to December 9, 1941, and are effective to termination of the war; cancellation is permitted either party on 6 months' notice or on resumption of official tin quotations on the London Metal Exchange. Payment for additional expenses incurred by producers in increasing their output is provided for.

¹⁰ An excellent résumé of the geology and mining practice in Netherlands East Indies was published in 1944 by the Netherlands and Netherlands East Indies Council of the Institute of Pacific Relations, Rockefeller Plaza, New York. The author, Alex L. Ter Braake, is general manager of the Tin Processing Co. smelter at Texas City, Tex.

The Tenti dam was not completed as originally designed. After negotiations with the Ministry of Supply the Nigerian Electricity Supply Corp., Ltd., took over the dam as it then stood and carried out some work to impound about two-thirds of the original amount of water contemplated.

Portugal.—Tin production in Portugal declined sharply in 1944 to 1,772 tons or about half the quantity produced in 1943. Operations were confined to a few mines operating on a very small scale at the close of 1944. Under laws and regulations in force during the past several years, all tin metal produced has been acquired on a monopoly basis by the Comision Reguladora do Comercio de Metais. No cassiterite as such was acquired, as Government purchases were confined to metallic tin only. The price paid producers was fixed at £1,350 per metric ton of metal, with a minimum of 99.50 percent tin. This Government agency also handled all local and export sales of metallic tin. The high price offered producers resulted in a boom among small mining and smelting operations. The high price paid by the Government for tin, plus selling expenses, and an export duty made prices unattractive to foreign consumers, consequently buying fell, stocks increased, and when communications with Germany were cut off in June 1944, following the Allied invasion of Europe, both Allied and German buying ceased. The Government was left with a relatively large stock of tin and has refused to buy any more or to allow it to be sold elsewhere or exported except from its stock at its price. Owing to this mining, virtually came to a standstill. The Portuguese-American Tin Co. and one or two other mines, however, continued working on a reduced scale by storing their product pending authority to dispose of it. Another factor contributing to the decline in output of tin was mining of low-grade tungsten, which fell to a very low level in 1944. Previously the mining of tungsten had been greatly stimulated by fantastic preclusive buying prices, but as this ceased in 1944 production of low-grade ores fell to a very low figure, and the byproduct tin output was affected proportionally. Spanish consumers are believed to have continued buying Portuguese tin at high prices, as they could get supplies from no other source. Some tin was purchased by Germany and flown out to Barcelona where it was transhipped by plane to Germany.

Spain.—Spain is not an important source of tin. Production has been supplemented by imports in order to meet requirements during recent years. Most of the tin produced in 1944 was from Murcia Province, where low-grade ores were mined with Government support. Tin extracted in connection with tungsten mining declined sharply during the latter half of 1944 as the closing of communications with Germany reduced the effective demand from that source. Although four plants were capable of refining tin, the small quantity of tin concentrates available was treated at the smelter of Industrias Reunidas Minero Metalurgica, S. A., Bilbao. Several small detinning plants were in operation at Huelva, Bilbao, and Barcelona. The price of metallic tin has been officially fixed at 47.50 pesos per kilo regardless of whether it is obtained from ore or detinning. The consumption of tin is Government-controlled.

Union of South Africa.—It has been estimated that the Zaaiplaats smelter produced about 1,250 tons of tin in 1944. The ores treated were derived from Central and South African sources where tin

mining was reported to have been very active. The smelting plant operated on a greatly increased scale as considerable quantities of concentrates were smelted on behalf of the National Supplies Control Board since October 1943. The Zaaiplaats Tin Mining Co. milled 44,270 tons of ore (41,420 in previous year) and recovered 188.5 long tons of concentrates (192.5 in previous year) during the year ended July 31, 1944.

United Kingdom.—With consumption cut approximately in half on a restricted basis, there was no lack of tin supplies for officially approved requirements of the United Kingdom during 1944. The principal use of tin in the United Kingdom during 1944 was for making tin plate and alloys mostly bronzes. Consumption by the tin plate mills probably increased slightly, but this was offset by reductions in the alloy field. Tin ores imported from Nigeria and Bolivia were less than in 1943; consequently, smelting operations were on a proportionally reduced scale in 1944. One smelter was reported closed as a result of wartime shortages of raw material to treat.

Mining in Cornwall was hampered by shortages of skilled underground labor and lower-grade ore. Production has been estimated as 1,100 tons in 1944. Measures are being taken to introduce a greater degree of mechanization into the underground operations. Cornwall producers have been receiving a guaranteed profit per ton of tin produced, but the price paid by the Ministry of Supply has not been disclosed. As a result of poor development and declining production the ore purchasing contract with East Pool and Agar, Ltd., has been suspended. The South Crofty mine was reported to have been taken over by the Ministry in December 1941,¹¹ and at East Pool and other operations the Government has been giving financial assistance. Exclusive of reexports and shipments from Government-owned stocks to forces abroad, exports of English refined tin were 3,144 tons in 1944 (12,251 in 1943). The sharp drop suggests a marked decline in Russian requirements. According to a statement by the Commissariat of Foreign Trade in Moscow, 29,400 tons of tin had been delivered to Russia by Great Britain since the beginning of the Russo-German War up to April 1944.

Tin-plate production in Wales was slightly higher than in 1943. The number of mills operating was virtually unchanged, but the average output per mill increased. Approximately one-third of the output is derived from the hot-strip process and the remainder from old-type cold-reduction plants. The redundancy scheme of the tin-plate manufacturers for reorganization and modernization of the industry has been accepted by the Board of Trade. The five principal firms concerned—Richard-Thomas/Baldwin combine; Guest, Keen, & Nettlefolds, Ltd.; the Briton Ferry Iron & Steel Co.; and the Llanelly Associated Co.—have agreed on the erection of a hot-strip mill for tin plate and sheets at Port Talbot, where the principal works of Baldwins, Ltd., and the Briton Ferry Steel Co., Ltd., are situated. Consideration also is being given to the establishment of cold-reduction plants at Llanelly and in one or two other districts. The Richard-Thomas/Baldwin combine referred to is the result of a merger during the latter part of December 1944 of the two largest sheet and tin-plate manufacturers in the United Kingdom. This new organization will thus control the major portion of the tin-plate output, and it is ex-

¹¹ *The Metal Bulletin* (London), No. 2363, Feb. 11, 1944, p. 7.

pected to be quite an important factor in postwar recovery of the tin-plate export trade of the United Kingdom. (The Welsh tin-plate industry, which ordinarily depended upon exporting 50 percent of its output, has been adversely affected by the war.) Before the merger Richard Thomas & Co., Ltd., had a continuous cold-strip mill and was reported to have ordered an electrolytic tinning unit. Official maximum selling prices of prime tin plate for the home trade have been 29s. 9d., per box, f. o. b. makers' works, and 30s. 9d., f. o. b. works' port for export. Production costs have been above the official selling price, and subsidy payments have been made to tin-plate makers from a central fund. The latest figure was reported to be 50s. per ton, and as the bulk of production averages 90 pounds per box the bonus represents approximately 2s. per box.

ARSENIC

GENERAL STATEMENT

A record domestic production of white arsenic was made in 1944 with an increase of nearly one-sixth over that of 1943. The substantial rise offset an approximate drop of 40 percent in imports, compared with 1943, and thus maintained new supply near the high mark of 1943. This favorable circumstance with a 15-percent recession from the 1943 peak consumption rate brought year-end stocks to the highest point since 1940 and 170 percent above the 1943 low point.

The quoted price of white arsenic remained at 4 cents a pound throughout 1944. Prices for arsenical insecticides were held at the ceilings fixed in 1943 by Maximum Price Regulation 315. General Preference Order M-152 of May 22, 1942, which provided for allocation of arsenic, was revoked September 13, 1944, but control was simultaneously extended under General Allocation Order M-300, Schedule 46.

DOMESTIC PRODUCTION

White-arsenic output in the United States in 1944 was 15 percent greater than in 1943 and exceeded the peak established in 1941 by 11 percent. As usual, byproduct output from copper and lead ore smelting was the principal source, but this was materially augmented by reduction of high-arsenic ores from the Gold Hill, Utah, area; by recovery from flue dust of the Gatchell Gold Mine, Potosi district,

Nevada, and from gold-tungsten ores of the Jardine Mining Co., Jardine, Mont. The Gold Hill ores have an arsenic content of about 18 to 30 percent and a small quantity of gold; Getchell Mine gold ores have a variable arsenic content that must be driven off by roasting before the gold can be recovered by cyanidation. At Jardine, arsenopyrite is widely distributed in the gold-lode system. The maximum white-arsenic output occurred in 1925-26, when massive arsenopyrite was mined in some sections of the property. Production was discontinued in 1936 but was resumed in 1944 after rehabilitation of the mill and arsenic plant. It has been reported¹ that recent mine production has an arsenic (As_2O_3) content of about 3 percent, although results obtained in the first half of 1944 indicate a lower tenor. Additional arsenic and arsenic compounds were derived from treatment of Canadian nickel-cobalt speiss and from speiss from the widely known Bawdwin, Burma, lead-zinc-silver mine. This material had been imported after the outbreak of the war in the Pacific.

Producers of arsenic included the American Smelting & Refining Co., Anaconda Copper Mining Co., Ferro-Enamel Corp. and Ferro Enamel Supply Co. (calcium arsenate), Jardine Mining Co., Shepherd Chemical Co. (sodium arsenite), and the United States Smelting, Refining & Mining Co.

¹ Excludes crude consumed in making refined.

² Compounds made directly from ores, flue dust, and speiss contained white arsenic as follows: 1942, 290 tons; 1943, 172 tons.

³ Partly estimated.

POSTWAR OUTLOOK

No substantial deviation from the use pattern developed in the past quarter century is anticipated. Roughly, three-quarters of the consumption of white arsenic has been for the preparation of agricultural insecticides used mainly to combat the cotton boll weevil, the codling and gypsy moths that cause widespread damage to apples and pears, and as herbicides. Of the remainder, the glass industry is the largest user and may account for 5 to 10 percent of total use. Adequate data are not available, but in the 20-year period 1920-39 consumption has apparently grown more than 50 percent, whereas the production of cotton and the fruits named has shown a substantially lower rate of change. A part of the greater rate of use may

¹ The history, economic and structural geology, and output of the Jardine Mining Co. and nearby districts have been described in a monograph by Dr. George A. Seager, *Gold, Arsenic, and Tungsten Deposits of the Jardine-Crevasse Mountain District, Park County, Mont.*: Montana School of Mines, Butte, Mont., Memoir 23, December 1944.

be attributable to a decline in price within the period, but quoted prices for white arsenic and calcium arsenate have been relatively stable near current prices since about 1925, and that of lead arsenate reasonably so for about the last 5 years of the period. Prices appear to have stabilized. No equally satisfactory and low-cost substitutes have been marketed commercially. Domestic production of the basic material, white arsenic, has kept pace with consumption. However, at no time has the domestic output been adequate to meet domestic requirements, and the United States will probably continue to be a substantial importer.

For the immediate future, a good market for all the probable domestic output of arsenic at or near the current price level seems assured, especially as world needs for foods and fibers will be at a high level. For the longer term the factors affecting domestic production are less favorable. The major one of price will be determined by the cost of imported arsenic and its relation to the cost of the byproduct material obtained principally in copper and lead smelting. After Atlantic shipping becomes available, prices cannot be expected to rise substantially because of the huge stocks of arsenic that have accumulated in Sweden as a byproduct from the treatment of the Boliden copper-gold-silver ores; these stocks are equivalent to several year's world requirements. The wartime development of effective new organic insecticides, such as DDT (dichloro-diphenyl-trichloro-ethane), may be strong competitors of arsenicals, although not yet sanctioned for commercial use. A downward trend in cotton price usually tends to contract acreage sown and correspondingly affects use of calcium arsenate. It is to be expected that a cotton price recession will follow withdrawal of wartime support or premiums and may be accentuated by competition from synthetic fibers. Exports of white arsenic and the agricultural arsenicals, measured in terms of arsenic, are much smaller than arsenic imports and therefore have no bearing on domestic production. Little change is expected in minor-use fields, and no important new applications have been described. On the whole, it appears that only low-cost or otherwise favorably situated domestic producers may retain their nearby competitive position into the more distant future.

FOREIGN TRADE²

Up to 1901 the United States was entirely dependent on foreign sources for its arsenic needs. Domestic production began in that year, but despite its rapid growth imports increased substantially, especially after the First World War, and reached a peak of 19,256 short tons in 1937, then declined to about the 10,000-ton level in 1940-41. In response to war-created demand, imports advanced to over 16,000 tons in 1942-43, but again declined to 9,965 in 1944. Since 1923, the first year in which the imports of white arsenic were clearly defined, Mexico with one exception (1923) has been the dominant supplier and in 1944 furnished 77 percent of the foreign supply, with virtually all the remainder from Peru, which appeared first as a source in 1943 with 103 tons.

² Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Exports of white arsenic were 22 percent above those of 1943 but were one-quarter under the 1939 peak. The United Kingdom was the destination of nearly one-half the total, with the remainder distributed to the Union of South Africa and other countries.

² According to U. S. Department of Agriculture there have been no imports of london purple since 1936.

³ 1940-42: As reported to Bureau of Mines by the producers; 1943-44: As reported by U. S. Department of Commerce.

⁴ Dealers exported an additional 1,077,244 pounds.

⁵ Not separately classified.

⁶ Figures cover July to December; not separately classified before July 1.

CONSUMPTION AND USES

In 1944, over-all domestic consumption dropped sharply about 15 percent from the 1943 record high. This resulted principally from military contract cancellations largely by the Chemical Warfare Service, which more than offset wider use in other fields.

Production of calcium arsenate, 100 percent Ca₃(AsO₄)₂, in consequence of low boll-weevil infestation was only 22,154 short tons in 1944, compared with 34,932 tons in 1943; lead arsenate (acid and basic) output was 45,352 tons in 1944, compared with 36,978 in 1943; and that of paris green was about at the 1943 rate of 1,650 tons according to the United States Department of Commerce.

In view of the early improved supply position, 3,000 tons of white arsenic were allocated to the glass industry, a fourteenfold increase over the 1943 figure; earlier war restrictions had forced the glass industry to turn to substitutes such as antimony, cerium, and sodium sulfate. The use of arsenical insecticides for protection of shade trees, nurseries, lawns, and golf courses was authorized in February 1944. The amount of arsenic used for dyestuffs dropped over 40 percent, whereas the tonnage allocated as a weed killer was nearly as much as the sum for the preceding 2 years. Although the quantity of wood given preservative treatments in 1943 was about 17 percent less than in 1942, the use of arsenicals dropped much more abruptly because of restrictions on use of arsenic. Wolman-salts (25 percent sodium arsenate) consumption was 385 short tons, compared with 654 in 1942, and zinc meta-arsenite use was only 27 tons, compared with 120 tons in the preceding year, according to the United States Forest Service. Sales of medicinal arsenicals, which are used for the treatment of syphilis, amoebic dysentery, yaws, trichomanas vaginitis, and African sleeping sickness, dropped to 20 million doses in 1944, compared with 30 million in 1943 and 33 million in 1942, according to the United States Public Health Service. The production of these drugs—neoarsphenamine, acetarsone, carbarsone, tryparsamide, arsenoxides (mapharsen, clorarsen, phenylarsine), and sulfarsphenamine—totaled 98,006 pounds in 1944, compared with 83,026 pounds in 1943, according to the War Production Board.

White arsenic consumed in the United States, 1942-44, by uses ¹

⁴ Gas purification, pharmaceuticals, cattle dip, paint, and other uses.

PRICES

The quoted price for white arsenic remained at 4 cents a pound throughout the year, according to the Oil, Paint and Drug Reporter. Maximum Price Regulation 315 of February 9, 1943, fixed the base price for lead arsenate in carlots at 11 to 11½ cents a pound. The ceiling base prices for other arsenical insecticides were fixed by an amendment on April 6, 1943, as follows (cents per pound in carlots): Calcium arsenate, 7 to 7½; paris green, 20 to 25; and london purple, 7 to 8.

STOCKS

The substantial cut in military requirements early in 1944 and the 37-percent decline in calcium arsenate output, while new supply was nearly equal to that in 1943, was reflected in a much improved year-end stock position over that of preceding years.

Year-end stocks of arsenic compounds in the United States, 1940-44, in short tons

¹ Arsenic is also believed to be produced in Czechoslovakia, Iran, Turkey, and U.S.S.R. Production figures are not available for these countries.

² Data not available; in 1936 to 1940, inclusive, estimate included in total.

³ January to June, inclusive.

⁴ August to December, inclusive.

⁵ Arsenic content of ores mined was as follows—1936: 23,312 tons; 1937: 20,954 tons; 1938: 21,480 tons. Data not available for later years.

Argentina.—Enough white arsenic has been available from Mexico to permit the industry to meet all requirements for calcium arsenate and paris green, but fruit growers are handicapped by a serious shortage of lead arsenate. Production of the latter material from mispickel ore in the Mendoza region is expected to amount to approximately 150 tons in 1944.³

Brazil.—Owing to a shortage in supplies, the Government set up controls over production and distribution of arsenic. Before the war, Belgium, Germany, Japan, and the United States were the principal suppliers; now only limited quantities (mostly in the form of insecticides) are available from the United States and the United Kingdom.

Virtually the total Brazilian arsenic production is derived from gold ores. In the first half of 1944, output, which was about 75 percent of the corresponding 1943 production, was as follows, with totals for the year 1943 in parentheses: St. John del Rey Mining Co., 314 metric tons (816), and Cia Minas de Passagem, 52 metric tons (141). The average value (5.64 cruzeiros a kilogram) in 1944 was about 8 percent above that for 1943.

Canada.—According to a preliminary estimate of the Dominion Bureau of Statistics, Canadian arsenic production in 1944 (1,272 short tons) was 81 percent of the 1943 volume, and the average value per pound declined 17 percent to about 6.7 cents. The major producers were the Beattie Gold Mines, Ltd., and the O'Brien Gold Mines, Ltd., both in the Province of Quebec. Refined arsenic was made by the first-named and by the Deloro Smelting & Refining Co., Ltd., Deloro, Ont.

Colombia.—The Instituto de Fomento Industrial planned to produce arsenic and to manufacture arsenic compounds at a plant near Samana, Department of Caldas.⁴

Great Britain.—The Long Ashton Research Station has reported outstanding results with DDT as an insecticide. It was suggested that it be given field trial as a substitute for lead arsenate.⁵

India.—India is dependent on foreign sources for its arsenic. Only very small and intermittent production from small and inaccessible deposits in northern Mysore and at Chitral in the Himalayan region has been recorded.⁶

Peru.—The Cerro de Pasco Copper Corp.'s plant, which began operation in June 1943, is estimated to have produced about 8,068 short tons of white arsenic during 1944. Although a contract with the Metals Reserve Company called for the delivery to the United States of 800 tons monthly in 1943-44, deliveries were 5,354 short tons in 1944 and 103 tons in 1943.

Sweden.—The excessive accumulations of white arsenic, believed to exceed 350,000 tons, and current production from Boliden's copper-gold-silver ore constitute a threat to other producing countries. This position is enhanced by the termination in May 1945 of the European phase of the World War, as all European requirements easily may be satisfied, thus curtailing the pressure on the United States and Mexico, the remaining important world suppliers. An invasion of Western Hemisphere markets may not follow for some time because of ship shortage and high freight rates. The Boliden Co. has en-

³ Foreign Commerce Weekly, Argentine Insecticides and Fungicides: Vol. 17, No. 9, Nov. 25, 1944, p. 24.

⁴ The Chemical Age (London), vol. 102, No. 1332, Jan. 6, 1945, p. 22.

⁵ Chemical and Engineering News, News Edition, vol. 23, No. 6, Mar. 25, 1945, p. 584.

⁶ Metal Bulletin (London), No. 2910, July 14, 1944, pp. 4-5; 10.

gaged in research work⁷ in an attempt to develop new markets. One result has been the substitution of zinc arsenate for lead arsenate. The zinc salt is reported to be more effective than the lead and to be less toxic to human beings. It may also be used as a weed killer, and it is believed that it can be applied for that purpose to a sown field without injury to crops. It has also been reported⁸ that licenses may be had for an arsenic treatment of lumber that makes it weather resistant.

U.S.S.R.—A novel method of manufacturing paris green has been reported⁹ by Soviet scientists. White arsenic is added to a boiling solution of copper oxide in acetic acid in place of the usual method of dissolving arsenic in soda lye and mixing the solution with copper sulfate and acetic acid. In the latter method the soda is lost as the sulfate in the filtrate, whereas in the proposed scheme the filtrate containing any unreacted copper and arsenic may be re-used.

The Soviet press reports that operations have begun at the recently discovered Azerbaidjan arsenic deposits.

Domestic production.....	752	Prices.....	754
Foreign trade.....	752	World review.....	754

GENERAL STATEMENT

Domestic refinery production of bismuth rose moderately in 1944 compared with 1943 but was offset by a decline in imports of nearly the same magnitude. Total stocks in the United States at the year end were but slightly above those at the end of 1943, a position obtained only through holding consumption closely to the new supply rate. Conservation measures instituted by the War Production Board early in 1943 were effective throughout 1944, essentially unmodified. Conservation Order M-295, bismuth chemicals, was revoked January 20, 1945, but its provisions, virtually unchanged, were embodied simultaneously in Schedule 88 of General Allocation Order M-300.

FUTURE OUTLOOK

Bismuth needs of the United States had been met from foreign sources until 1906 when domestic recovery began. Subsequently, and even through the several depressions, the metal and salts as well continued to be received from abroad. Domestic output, though increasing, did not overtake expanding requirements. These general trends are expected to continue, with the result that all economic domestic production should be absorbed readily.

Changes in the use pattern indicate wider markets. In the early 1930's consumption was of the order of one-third million pounds, and probably not over one-quarter was used for other than medicinals or cosmetics. About that time low-melting-point alloys—approximately one-half bismuth—began to find new uses, such as a filling or backing in the bending of thin-walled tubing and other light sections; these fillings are recovered by heating the formed material to the very low melting point of the bismuth alloy. By 1941 consumption had probably exceeded 1¼ million pounds, and the nonmedicinal-cosmetic application share had risen to about 40 percent. The needs for the alloys were so large that the War Production Board was forced from 1942 on to hold the medicinal-cosmetic percentage to about 45 percent despite peak domestic production and imports. Many of the war-

time uses, including some that are still secret, will probably persist.¹ When restrictions on the use of bismuth are lifted consumption probably will rise well above that of the immediate prewar years. Demand can be expected to taper off when industrial inventories of alloys have increased sufficiently to carry on shop operations, most of which are essentially nondissipative.

DOMESTIC PRODUCTION

The output of refined bismuth in the United States in 1944 was little more than 2 percent above that of 1943; actual production data may not be given by the Bureau of Mines. Exploration work of the Bureau of Mines in the Alta district, Utah, begun in 1943, disclosed several bismuth-bearing ore bodies containing 1 to 5 percent bismuth.

Domestic producers (smelters and refineries) were, as they have been for 10 years or more, American Smelting & Refining Co., Anaconda Copper Mining Co., and the United States Smelting, Refining & Mining Co. The metal was obtained as a byproduct in the smelting of domestic and foreign lead and copper ores, from Mexican bismuth-lead bullion, and from a small volume of South American bismuth ores. The Cerro de Pasco Copper Corp., New York, is the largest importer and consumer of bismuth.

FOREIGN TRADE²

Imports.—Bismuth-ore imports comprised 78,564 pounds (46.7 percent Bi) from Argentina, 12,901 pounds (53.2 percent Bi) from Bolivia,³ and 27,274 pounds (27.7 percent Bi) from Chile, according to the Foreign Economic Administration. Mexican output (see world-production table) is almost entirely in the form of bismuth-lead bars, which are imported into the United States for refining. All refined-metal imports, 1940–44, originated in Peru.

Bismuth imported for consumption in the United States, 1940–44

CONSUMPTION AND USES

Domestic consumption was reduced nearly 27 percent from the 1943 level to hold use close to new supply and thus maintain the Government-owned stock pile near the desired level.

The wartime importance of metallurgical applications and limited supply brought about striking changes in distribution. Pharmaceutical and cosmetic uses accounted for 40 percent of the bismuth consumed and metallurgical use for most of the remainder, the converse of the 1941 relationship. Most commercial bismuth alloys have low melting points and tend to expand on solidification. These properties make them especially useful as a support for thin-walled tubing to prevent wrinkles or collapse while being formed; to hold parts in dies or machine tools; for the chucking of irregularly shaped pieces; for nitriding furnace seals; as fusible plugs in fire protective devices; as short-run forming dies; and in ammunition and substitute solders. New uses are electroforming of intricately shaped parts to close tolerances and as a sprayed coating on patterns and core boxes to give smooth surface finish and sharp contour reproduction. Additions of small quantities of bismuth or bismuth-lead to aluminum alloys, stainless, manganese, and carbon steels, and some other alloys have shown marked increases in machinability.⁴ Bismuth pharmaceutical products are used principally as antisypilitics but also in indigestion remedies and in cosmetic powders.

Bismuth consumed in the United States, 1942-44, by uses

¹ Estimated from producers' and importers' shipments.

² From War Production Board.

³ Includes 208,632 pounds in ammunition solders in 1943 and 211,789 pounds in 1944; most of remainder in tin-savng solders.

⁴ Includes 40,889 pounds in fuse alloys and 31,912 pounds in rectifier coatings in 1943 and 91,096 and 72,192 pounds, respectively, in 1944.

⁵ Trethaway, J. D., Work cited in footnote 1.

STOCKS

Producers', distributors', and consumers' bismuth inventories at the year end were less than 3 percent larger than at the beginning of the year; Government-owned Metals Reserve Company metal stocks increased.

PRICES

Metallic bismuth continued to be quoted throughout 1944 at \$1.25 per pound, ton lots, according to E&MJ Metal and Mineral Markets. Base prices of bismuth compounds, likewise unchanged, were listed by Oil, Paint and Drug Reporter as follows, per pound:

Chloride.....	\$2. 85	Oxychloride.....	\$3. 10	Subnitrate.....	\$1. 20
Citrate.....	2. 75	Subbenzoate.....	3. 40	Subsalicylate.....	2. 50

Nitrate.....	1. 30	Subiodide.....	4. 13		

WORLD REVIEW

Estimated world production in 1944 was about 1,200,000 kilograms (2,640,000 pounds). The major producers were the United States, Peru, Canada, and Mexico.

*World production of bismuth, 1939-44, by countries, in kilograms*¹

¹ Bismuth is believed to be produced also in Brazil, Burma, China, Germany, Japan, Norway, Rumania, Sweden, Uganda, U. S. S. R., United Kingdom, and Yugoslavia. Production figures are not available for these countries, but estimates by author are included in total.

² In ore.

³ Content of ore exported to United States.

⁴ Data not available. Estimate included in total.

⁵ Partly estimated. Excludes content of some bismuth-tungsten concentrates.

⁶ Excludes bismuth content of tin concentrates exported.

⁷ Production included in total; Bureau of Mines not at liberty to publish figure.

Canada.—In 1944 the total Canadian production was derived from treatment of lead-silver ores by the Consolidated Mining & Smelting Co., Ltd., at Trail, B. C. Most of the 70-percent drop in output in 1944 was attributable to exhaustion of residues accumulated before 1942 and in part to a 30-percent decrease in lead production in 1944.

Peru.—The statement concerning primary sources of bismuth reported in the Bismuth chapter of Minerals Yearbook, 1943, was in error in attributing 80 percent of the production to lead or lead-silver mines. Bismuth is present in very small quantities in a great many of the copper and lead ores treated by the Cerro de Pasco Copper Corp. Dusts collected at its copper and lead smelters are treated in

the bismuth refinery that has a daily capacity of 4,000 pounds refined (99.99 percent Bi) bismuth. Exports of refined bismuth in 1944 were 446 metric tons, of which about 180 tons were destined to the United States and the remainder to the United Kingdom.

Spain.—No production was reported in the Civil War period, 1936–39, but from 1940–44 concentrate output (about 25 percent Bi) ranged from about 40 to 50 metric tons annually, except in 1942 when it rose to about 125 tons. In this period metal output averaged a little over 10 tons a year, which was about in equilibrium with Spain's domestic requirements. The principal source of bismuth is in Córdoba Province. In 1942 the price of metal had been fixed at 50 pesetas a kilogram, but it was raised to 90 pesetas about the end of 1943 in order to stimulate mining.⁵

United Kingdom.—Demand for bismuth and alloys for metallurgical use remained strong throughout the year. The price was unchanged at 6s. 3d. a pound in 5-cwt. lots in 1944.

SUMMARY

Production of primary magnesium in the United States in 1944 totaled 157,100 short tons—14 percent less than in 1943 (183,584 tons). Owing to decreased war requirements and growing stocks, production was cut back 83 percent in several stages between March and December 1944.

¹ Ingot equivalent.

² Lowest nominal price (New York) for primary metal ingot 99.8 percent pure, carlots.

³ Magnesium metal in primary form.

Magnesium sold or used during the year totaled 146,585 tons, 14 percent less than the 1943 figure of 170,267 tons. Actual consumption of magnesium in the form of primary metal and alloy (excluding secondary) was 132,698 tons (magnesium content). Exports in the form of metal totaled 21,001 tons; imports were negligible.

In October 1944 all restrictions on the use of magnesium were removed by the War Production Board.

World magnesium output is estimated at 235,100 metric tons in 1944, 13 percent less than the record production of 1943. Axis and Axis-dominated countries controlled about 29 percent of the world total, whereas the United Nations furnished 71 percent, according to estimates.

PRODUCTION

Raw materials.—Magnesium, the lightest and newest of the industrial metals, is produced from a wide variety of sources. Sea water,

dolomite, magnesite, underground brines, and residues from potash manufacture were the raw materials used commercially in the United States in 1944.

Sea water was used as a primary raw material in two Texas electrolytic plants and in conjunction with dolomite at a California carbo-thermic process plant. Dolomite alone was used at six ferrosilicon-process plants in Connecticut, New York, Ohio, Michigan, Washington, and California; dolomite with calcium chloride waste liquors was used at an electrolytic plant in Ohio and one in Louisiana; and dolomite and byproducts of potash manufacture were used at Carlsbad, N. Mex., to produce magnesium chloride for an electrolytic plant in Texas. In Nevada a large deposit of magnesite was mined for use in a large Magnesium Elektron electrolytic process plant in Las Vegas. Two plants in Michigan used well brines containing magnesium chloride in electrolytic cells for the production of magnesium.

Primary magnesium.—Production of primary magnesium in the United States in 1944 totaled 157,100 short tons (ingot equivalent), a decrease of 14 percent from the 183,584 tons produced in 1943. These figures represent the ingot produced directly from Dow-type electrolytic cells plus a magnesium "ingot equivalent" of the raw and crystal metal obtained from other processes of manufacture which experiences some loss when melted down into ingot form. The total output of all primary magnesium in the various forms, making no allowance for melting losses, was 161,935 tons in 1944 compared with 190,025 tons in 1943. A quantity of microscopic magnesium dust produced during 1944 was not included in the production figures because it is made directly into an incendiary mixture ("goop") and does not actually enter the market as magnesium metal.

At the beginning of 1944 surplus stocks of magnesium ingot had risen to about 24,000 short tons. A recommendation was made by the War Production Board to accumulate a reserve equivalent to about 2 months actual requirements to be held at Government-owned plants. In view of this recommendation and the fact that stated requirements remained high, no substantial cut backs in production were made until March. The annual rate of output in the first quarter of the year averaged nearly 248,000 tons, or about 85 percent of the country's rated capacity.

The initial cut-back in the magnesium-producing industry was effected on February 1 with a 33-percent curtailment at the ferrosilicon-process plant of the Defense Plant Corporation (DPC), operated by Amco Magnesium Corp. at Wingdale, N. Y. The cut-back amounted to only 1,650 tons a year or less than 1 percent. Later, as output of new metal threatened far to outstrip consumption plus planned stock-pile accumulations, further cut-backs were ordered. On March 1 cut-backs were made at three more ferrosilicon-process plants, totaling 37,000 tons of annual capacity, distributed as follows: Ford Motor Co. DPC plant, Dearborn, Mich., 20,000 tons or 100 percent; Electro Metallurgical Corp. DPC plant, Spokane, Wash., 12,000 tons or 50 percent; and Permanente Metals Corp. DPC plant, Manteca, Calif., 50 percent or 5,000 tons. On April 1 the Mathieson Alkali Works, Inc. DPC electrolytic plant, Lake Charles, La., was closed, representing a 27,000-ton cut-back, and the Basic Magnesium, Inc., DPC M. E. L. process plant at Las Vegas, Nev., was cut 40

percent or 22,400 tons. Dow Magnesium Corp. was ordered to curtail output 40 percent or 14,400 tons a year at its DPC plant, Marysville, Mich., on May 1, and on June 1 orders were given to close the Permanente Metals Corp. Manteca plant and the Amco Magnesium Corp. Wingdale plant, representing 8,350 tons of capacity. On July 25 the remaining 21,600 tons capacity of Dow Magnesium Corp. at Marysville was closed; an additional 20 percent or 11,200 tons at the Basic Magnesium Las Vegas Plant and 16 percent more or 4,000 tons at the Electro Metallurgical Corp. plant were closed. During August production dropped below an annual rate of 150,000 tons for the first time since February 1943, the growth of surplus stocks had been slowed, and

FIGURE 1.—Trends in production, exports, and quoted price of primary magnesium, 1935-44.

ingot stocks at military facilities had been greatly reduced. However, requirements of magnesium were cut still further in late summer, and on August 31 the remaining 40 percent of capacity (22,400 tons) was closed at the Las Vegas plant of Basic Magnesium, Inc.; the International Mineral & Chemical Corp. DPC plant, Austin, Tex., was closed (12,000 tons); and the Dow Magnesium Co. DPC plant, Velasco, Tex., was curtailed 50 percent or 18,000 tons. Thus, by September 1, 200,000 tons of an annual capacity of 293,000 tons had been cut by Government order. On September 25 Diamond Magnesium Co. was ordered to curtail output at its DPC plant, Painesville, Ohio, by 25 percent or 4,500 tons; and on October 15 a 60-percent cut or 3,000 tons was announced for New England Lime Co. at Canaan, Conn. The final cut-backs of the year came on November 25, closing the Dow Magnesium Corp. plant at Marysville (18,000 tons or 50 percent), effecting another 25-percent cut at the Diamond

Magnesium Corp. plant (4,500 tons), and reducing output 40 percent at the Magnesium Reduction Co. DPC plant, Luckey, Ohio (2,000 tons). By January 1, 1945, the War Production Board had ordered the closing of 232,000 tons or 79 percent of total domestic capacity. Voluntary reductions at privately owned plants added to the War Production Board cut-backs were such that in December the entire industry operated at an annual rate of about 17.4 percent of total rated capacity.

Of all the primary magnesium plants closed during 1944 only two—the Ford Motor Co. plant at Dearborn, Mich., and the Mathieson Alkali Works, Inc., plant at Lake Charles, La.—were not held in stand-by condition. However, part of the Electro Metallurgical Co. plant at Spokane, Wash., has been converted to the production of metallic sodium. The Basic Magnesium, Inc., plant at Las Vegas, Nev., has also been partly converted; the Western Electrochemical Co. installed equipment in cell unit 4 for the production of potassium perchlorate, and the Rheem Mfg. Co. took over part of the plant to produce 81-mm. mortar shells and rocket projectiles for the Army and Navy. New England Lime Co., Canaan, Conn., is using part of its plant for the production of metallic calcium.

Production, sales, exports, and apparent consumption of primary magnesium in the United States, 1940-44, in short tons

	Production		Sales	Exports	Apparent consumption ¹
	Raw, crude, and pure ingot	Ingotequivalent			
1940.....	6,261	6,261	6,411	² 834	5,577
1941.....	16,295	16,295	15,528	1,549	13,979
1942.....	³	48,963	47,420	4,045	43,375
1943.....	190,025	183,584	170,267	⁴ 14,720	155,547
1944.....	161,935	⁵ 157,100	146,585	⁶ 4,830	141,755

¹ Does not consider fluctuations in consumers' stocks and metal derived from scrap. Withdrawals from producers' stocks totaled 150 tons in 1940; additions to producers' stocks totaled 767 tons in 1941; 1,643 tons in 1942; 13,317 tons in 1943; and 10,615 tons in 1944.

² Of the 859 tons of metal exported, 25 tons consisted of magnesium alloy.

³ Not available.

⁴ Of the 35,631 tons of metal exported, 20,911 tons consisted of magnesium alloy.

⁵ Does not include magnesium content of incendiary mixture produced direct.

⁶ Approximately 77 percent of the 21,001 tons exported was magnesium alloy.

Secondary magnesium.—Recovery of secondary magnesium totaled 14,185 short tons (including secondary magnesium incorporated in primary magnesium ingot) in 1944 (11,404 tons in 1943) and required the consumption of 17,014 tons of magnesium scrap, which was almost entirely new scrap. Of the quantity of magnesium recovered, 13,379 tons were as ingot, 235 went into castings, 23 into aluminum alloys, 7 into lead and zinc alloys, and 541 into chemicals and incendiary products. Additional information on secondary magnesium will be found in the chapter on Secondary Metals—Nonferrous.

CONSUMPTION

Virtually all the magnesium consumed during 1944 went into military uses, even though restrictions on its use for civilian items were revoked in October. The most important end uses of the metal were

incendiary bomb casings and aircraft engine parts, frames, landing gear, and accessories. Other important uses included rocket-launcher tubes, powder for incendiaries, flares, and tracers, and as an alloying metal with aluminum. Apparent consumption of pure primary magnesium in 1944, calculated by subtracting exports from sales, totaled 141,755 short tons compared with 155,547 tons in 1943, a decrease of 9 percent.

Consumption of primary magnesium and magnesium alloy (excluding secondary) in 1944 totaled 132,698 tons (magnesium content). No comparable figures are available for earlier years, because previous consumption surveys measured the quantities of magnesium structural and nonstructural products used. The survey of consumption conducted in 1944 measured use of primary and alloy magnesium ingot in production of the various structural and nonstructural products. Of the 132,698 tons consumed, 111,790 tons (84 percent) were used in the production of structural products (castings, sheet, structural shapes, and forgings); and 20,908 tons or 16 percent were consumed in other uses, including powder, alloys with other metals, and miscellaneous uses. Castings, including sand, die, and permanent mold types, was the largest single use for the metal, taking 105,119 tons of the total.

Actual domestic consumption of primary magnesium (ingot equivalent and magnesium content of magnesium-base alloy) in 1944, by uses

¹ Includes primary metal consumed in making secondary alloy.

PRICES

Throughout 1944 the base price of standard four-notch magnesium ingot remained at 20.5 cents a pound under Maximum Price Regulation 314, as amended. On March 11, 1944, magnesium powder, dust, and similar material were removed from the provisions of the General Maximum Price Regulation and placed under MPR 314 by Amendment 5. A ruling permitting alloys not formerly sold in ingot form to be sold at differentials above previously established ceilings became effective on October 2, 1944, in Amendment 6 to the magnesium price regulation. All alloys had been given a ceiling price of 23 cents a pound except four specific alloys, which were given higher ceilings; this amendment expanded the listing to provide specific prices for all ASTM alloys. Also added was a provision requiring that the maximum price of any alloy not listed shall be one approved by the Office of Price Administration and after approval shall be the maximum price for all subsequent sales by the same seller unless approval is withdrawn. Sales of less than 500 pounds of all alloys not listed in the price regulation were exempted from pricing; this provision

relieves industry of applying for approval of prices for items that will not be sold commercially, although such sales must be reported to the Office of Price Administration.

FOREIGN TRADE¹

Imports in 1944 of magnesium in all forms, all of which came from Canada, totaled 120,421 pounds (60 tons) valued at \$54,966 and consisted of 54,400 pounds of metal and scrap; 1 pound classified as sheets, tubing, ribbon, and other forms; and 66,020 pounds of powder.

Exports of magnesium from the United States, 1943-44

	1943		1944	
	Short tons	Value	Short tons	Value
Magnesium metal in primary form.....	135,631	\$16,272,607	21,001	\$9,799,833
Magnesium metal in other forms.....	2,674	1,478,141	1,597	987,048
Magnesium powder.....	2,126	1,207,429	1,600	2,301,293

¹ Includes 20,911 tons of magnesium-base alloy.

² Includes 16,171 tons of magnesium-base alloy.

Exports of metal in primary form included 15,958 tons that went to the United Kingdom, 4,996 to the U. S. S. R., 40 to Mexico, 5 to Canada, 2 to Brazil, and less than 1 ton each to Chile and the Union of South Africa. Of the magnesium metal in other forms, 999 tons were destined for the United Kingdom, 444 for the U. S. S. R., 93 for Mexico, 57 for Canada, 3 for Australia, and less than 1 ton each for Uruguay, Tunisia, and the State of Bahrein. Magnesium powder exported during 1944 included 1,583 tons shipped to the United Kingdom, 13 to Canada, 3 to Australia, 1 to Sweden, and less than 1 ton each to Algeria, Brazil, Mexico, and the U. S. S. R.

In 1944 exports of magnesium metal in primary form were equivalent to about 13 percent of the total domestic production compared with 19 percent in 1943.

WAR MEASURES

On October 5, 1944, Preference Order M-2-b, restricting the use of magnesium, which had been in effect since November 14, 1941, was revoked by the War Production Board. Simultaneously the Board issued Order M-2-c, which provides that all restrictions on the use of magnesium contained in other War Production Board orders no longer apply. However, restrictions in other orders as to the quantity of an article that may be made or as to its size and type remain applicable, even if the article is made wholly of magnesium. Order M-2-c states that persons wishing to obtain magnesium or its products may place rated or unrated orders with their normal suppliers without approval of the War Production Board, although such delivery orders are subject to priority regulations.

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

TECHNOLOGIC DEVELOPMENTS

Progress continued in 1944 in the field of alloying and fabricating magnesium, especially wrought alloys. A new sheet alloy, Dowmetal 251 X, having 5 percent aluminum and 1 percent zinc and being substantially tougher and more ductile than the previous sheet alloy, was announced during the year. Heat treatment for extruded alloys of the 8-percent aluminum, 0.5 percent zinc-type was developed with minimum yield strengths of 30,000 pounds per square inch in tension and compression.

During 1944 and early 1945 several publications appeared giving descriptions of processes used for producing magnesium and of laboratory investigations of other processes not used commercially. Much of the work referred to was done in the period from 1941 to 1943, but the appearance of more complete reports during 1944 warrants mention herein.

In July 1941 work was initiated at the Boulder City, Nev., Experiment Station of the Bureau of Mines² on processes that required minimum reliance on value of byproducts and could meet competition from present processes by using low-grade magnesite and dolomite situated near large blocks of firm power supply. Development has progressed for over 2 years on a process that appears to offer some promise and is based on electrolytic decomposition of magnesium oxide dissolved in a fused magnesium chloride bath. Investigations of this process are continuing.

Investigations on a process for producing magnesium from olivine have proceeded through the pilot-plant stage under the direction of the Tennessee Valley Authority.³ Magnesium chloride suitable for electrolytic reduction to magnesium metal was prepared from olivine by extraction with hydrochloric acid and subsequent purification. The olivine used was from Balsam, N. C., and the deposit had been shown to be typical of the high-grade olivine available at several localities in North Carolina.

Data gathered on retorts used in the ferrosilicon process for production of magnesium from dolomite showed that increased life of retorts with present alloys is possible only by resorting to mechanical means, such as increasing the wall thickness, using reinforcements, and expanding the retort with compressed air each time collapse occurs.⁴

Several interesting papers giving operating data and general descriptions of processes in use during 1944, including the carbothermic process,⁵ the ferrosilicon process,⁶ the Dow sea-water process,⁷ and the Dow process as used by Diamond Magnesium Co.,⁸ are to be found in the technical literature in the past year.

The production of magnesium halides from slaked, calcined dolomite by reaction with a readily hydrolyzable organic halide containing a

⁸ Avery, J. M., and Evans, R. F., Production of Magnesium at Painesville, Ohio: *Metals Technol.*, February 1945, Tech. Pub. 1829, 8 pp.

labile halide atom is described in United States Patent 2,338,876. Recovery of the magnesium content of sea water by an improved method to obtain the magnesium in the form of partly hydrated magnesium chloride, substantially free of impurities normally present in the sea water, is the subject of United States Patent 2,342,666. The process involves adding lime or another alkali to the sea water and precipitating the magnesium content as magnesium hydroxide. This product is then treated with calcium chloride and carbon dioxide, resulting in the formation of magnesium chloride solution and precipitated calcium carbonate. After purification the magnesium chloride is evaporated to dryness.

The direct reduction of magnesium and zinc carbonates or oxides to elemental form is described in United States Patent 2,364,742. The compound is mixed with coke and subjected to a blast of highly preheated air which causes combustion of the coke and raises the mixture above the reduction temperature of the metal compound. Then the air blast is replaced by a methane blast, liberating the metal in vapor form. The reaction is endothermic and thus requires alternate blasts of preheated air and methane to maintain output.

A process for pretreating magnesium dust produced by the carbothermal reduction process from magnesite to remove occluded natural gas before tableting or pelleting, was patented by Fritz J. Hansgirk (United States Patent 2,367,020). By this invention the magnesium dust is heated to a temperature at which it becomes plastic (300° to 360° C.), then subjected to a gliding compression, which can be obtained by passing the material between steel rollers having different peripheral speeds, and finally charged to pelleting machines which form the treated flakes into very hard solid pellets. Thus the distillation process can be carried out without causing any flying dust, and the metal collected by condensation is of high purity, according to the patent claims.

Welding in an inert atmosphere, such as helium or argon, prevents ignition of magnesium during welding and is described in United States Patent 2,342,086. Welding fluxes are not used in this method, and the weld is backed by magnesium or other material. In order to maintain the structural strength of the part welded, the weld section has to be increased about 100 percent in area.

POSTWAR OUTLOOK

Capacity to produce primary magnesium in the United States totaled 293,000 short tons annually in 1944, a quantity roughly 90 times that of prewar (1939) output. The tremendous expansion of this industry to meet the demands of war is unequalled by that of any other major metal. At the beginning of the European War in 1939, magnesium production was a comparatively small industry in which there was only one producing company. This company, Dow Chemical Co., produced the metal in connection with its chemical operations at Midland, Mich., and conducted extensive research on fabrication and new uses for magnesium in attempting to obtain its acceptance as a major metal. The potentialities of magnesium as a structural metal had long been recognized because of its extremely light weight and its high strength:weight ratio in alloy form. However, before the war fabrication of magnesium had not advanced enough to cause

its wide acceptance for structural use. Pyrotechnic, alloying, and deoxidizing uses claimed a major share of the output, although structural uses were growing.

During the war two additional privately owned plants were constructed—one by Dow and one by Permanente Metals Corp.—and 12 plants were built for the Defense Plant Corporation by various companies. In addition, many fabrication plants were constructed or converted from other metals to meet needs for magnesium permanent mold, die, and sand castings, as well as for extrusions, forgings, and sheet. During 1943 and the first half of 1944 magnesium assumed critical importance in incendiary bomb casings and in aircraft components. Demands changed constantly owing to shifts in military operations and to improvement of weapons and late in 1944 experienced a large decrease. As a result operations in the industry at the end of 1944 were at only 17 percent of capacity even with a two-front war in progress and with no restrictions on civilian use. Such a drop in demand for the metal is not conducive to optimism as to the immediate postwar outlook for magnesium. A survey of the wartime record leaves no doubt that the industry was greatly overexpanded, even for war, but the great difficulty in predicting war demands made this inevitable. The fact remains, however, that both private industry and Government possess magnesium-producing facilities far in excess of any demand foreseeable for at least a decade after the war.

The price of magnesium has dropped sharply since 1939, falling from 30 cents a pound to 20.5 cents. At present on a volume basis magnesium is cheaper than aluminum, although on a pound basis it is one-third more expensive. With the larger facilities now in use—particularly the efficient sea-water plants—there is no reason for believing that the downward price trend will be arrested at 20.5 cents. The wartime price reduction alone should result in increased demand in the postwar period compared with prewar; further decreases in price undoubtedly will be reflected in greater consumption for existing uses, development of new uses, and an advantageous competitive position in fields now dominated by other metals. An improvement in magnesium's competitive position is not assured, however, as the price of aluminum—a principal competitor—has also been experiencing a downward trend. As with aluminum, the first cost of magnesium in ingot form is not necessarily the decisive cost factor in using the metal in fabricated forms. The costs of casting, rolling, forging, and extruding the metal determine to a considerable extent its price to the consumer. Thus a price reduction of 20 percent in ingot metal may mean only a 5- or 10-percent reduction in the cost of the fabricated article. It seems reasonable to assume, however, that, when techniques of fabrication developed during the war, together with the present modern fabricating facilities, are put to use for civilian output, the cost of fabricating and forming will be reduced.

Magnesium stocks held by the Government and at producing, fabricating, and consuming plants at the end of the war may well represent several years "normal" postwar peacetime consumption. Therefore, the question of how this excess material is to be handled is very important. Stocks of metal in all forms at the end of 1944 are estimated to have been between 75,000 and 100,000 short tons. Even taking the lower estimate, these stocks represent nearly 25 years' supply at the 1939 rate of domestic consumption. Under the

Surplus Property Act of 1944 (Public Law 457—78th Cong.), however, magnesium is considered a "strategic metal," and according to section 22, subsection (a), all Government-owned accumulations shall be transferred to a stock pile under the Procurement Division of the Treasury. This provision will alleviate the stock situation greatly, but industry-owned magnesium surpluses after the war may still be considerable in terms of prewar consumption.

Estimates of postwar consumption of magnesium have varied widely and have ranged from 10,000 to 250,000 tons a year. A glance at the production and consumption record of magnesium from its beginning in the United States in 1915 makes this latter estimate seem almost ridiculously high unless it is intended for some period far in the future. It does not appear reasonable to prognosticate a consumption of more than 75,000 tons a year by the fifth year of peace, and even this figure is regarded as wishful thinking by many experts. Owing to its light weight, magnesium should find new and expanded uses in fields where that property can be used to the fullest advantage, such as in truck bodies, railroad rolling stock, terminal freight facilities, less-than-carlot containers, airplanes, portable tools, industrial machinery, and other items. Consumer goods, such as portable mechanical dishwashers, lawn mowers, and wheelbarrows, offer possibilities for increased use of the metal. In addition, the chemical and alloying uses of magnesium may take a substantial share of the output.

Raw materials for the manufacture of magnesium metal are widespread, and no supply problem exists. Sea water is available as a raw material wherever the ocean shore marks the United States border; dolomite is found in many States in abundant quantities as a common rock; brines high in magnesium chloride are found in Michigan, Kansas, Utah, and other States; and magnesite—the least abundant of magnesium ores—is found in California, Washington, Nevada, and other States. In addition, potential raw materials, such as serpentine and olivine, although not as widespread as some other possible magnesium ores, are found in large deposits in several Eastern and Western States.

The domestic magnesium industry is in an excellent position to compete with producers in other countries for world markets of both ingot metal and fabricated products. Mass production techniques should enable domestic articles made from magnesium to compete to advantage with other nations in foreign markets.

Owing to its abundance and light weight, magnesium should become one of the important nonferrous industrial metals of the future. When that time will arrive it is not possible to say, but it does not seem likely to be within the next decade. Continuously advancing technology, greater stress on weight saving, and probable lower future costs appear to insure magnesium a promising future.

WORLD PRODUCTION

World output in 1944 is estimated at 235,100 metric tons, or 13 percent less than the all-time record production of 269,800 tons estimated for 1943. It is believed that the bulk of the wartime expansion programs in the various foreign countries, with the possible exception of Japan, were completed by 1944, and in fact production was con-

siderably reduced by curtailments of excess output by the two largest magnesium producers among the United Nations—the United States and the United Kingdom. The statistical data upon which the estimates of production by the Axis countries are based are very meager, but it is believed that about 29 percent of the world output was under Axis control and about 71 percent under United Nations control. World production in 1945 is expected to be considerably reduced owing to the surrender of the Axis Nations in Europe.

¹ Actual production.

Canada.—Canadian production of magnesium, which increased 49 percent in 1944, was not affected by the large cut-backs in United States output, since orders from Great Britain continued to demand all that could be produced. The only plant producing magnesium was at Haley's Station near Renfrew, Ontario, operated by Dominion Magnesium, Ltd., and using the Pidgeon ferrosilicon process. The company owns the world patents on the process and has first option to buy the plant from the Dominion Government at the end of the war. Production costs, high at first, were reportedly down to 21 cents a pound in the spring of 1944, and it was believed that this figure could be substantially reduced with further operating experience to a point competitive with magnesium made by electrolytic methods.

The raw material, dolomite, used in the plant, is obtained from a deposit at the plant site. It is a high-purity crystalline dolomite of the Grenville series, and analyses of the material show a magnesium oxide content ranging from 20.48 to 21.55 percent, with only 0.25 to 0.65 percent insolubles.

Mid-Canada Magnesium Mines, Ltd., plans to begin construction at an early date of the first unit of a magnesium plant near Renfrew, Ontario.⁹ This unit will cost \$100,000 and will have a capacity of 1,500 pounds of refined metal per day. It is claimed that magnesium can be produced from dolomite for 10 cents a pound by the process to be used in the plant—the Keemle electrothermic process.

France.—No serious damage was done to any of the four French magnesium plants as a result of the war or German occupation. The plant of Compagnie Alais, Froges et Camargue at St. Auban, Basses Alpes, uses the I. G. Farbenindustrie process to produce magnesium

⁹ Iron Age, Canadian Firm Plans Magnesium Refining: Vol. 154, No. 14, October 5, 1944, p. 110.

from magnesite and has an annual capacity of 1,560 metric tons. The same process is used by the Société d'Électro-chimie, d'Électro-metallurgie et des Aciéries Électriques d'Ugine at Jarrie, Isere, in a plant which has an annual capacity of 1,800 metric tons. The Société des Produits Azotes at Lannemezan, Étes-Pyrenees uses the Murex, Ltd., carbide-reduction process in its 1,200-ton a year plant. Small quantities of magnesium are also produced by the Société Bozel-Maletra et Villard, Savoie. Grecian magnesite is the raw material used at the first three plants mentioned, but no data are available on operations of the fourth company. According to statistics issued by the Société Général du Magnesium for 1941 to 1944 only the Isere plant operated during that period. All production apparently ceased late in 1944, and the prospects for the industry in 1945 depend on the availability of magnesite.

United Kingdom.—The British price for magnesium was stabilized at £168 a long ton throughout 1944, or almost double the recently reduced price of aluminum in the United Kingdom. Converted to United States currency, this price is the equivalent of 30.225 cents a pound compared with the United States price of 20.5 cents. A report of the Select Committee on National Expenditure stated that much of the expanded wartime output cost even more to produce than the present market price. Production during 1944 is believed to have been considerably reduced, owing to cessation of operations at one of the four producing plants and curtailment of output at two others. Probably more than half of the magnesium requirements of British industry were met through imports from the United States and Canada.

SUMMARY

Government control of antimony was considerably less severe in 1944 than during the previous year. However, toward the end of the year increasing military demand for the relatively new antimony-consuming fire-retardant paints and flameproofed textiles, coupled with a diminishing supply of antimony available for consumption, necessitated a return to strict control under War Production Board General Preference Order M-112, as amended, effective February 10, 1945. The order limited inventories of ore to 45 days' supply and of all other forms of antimony to 30 days' supply.

Domestic production of antimony ore in 1944 decreased 20 percent below the 1943 output, the total metal content of the ore declining 15 percent. Antimony contained in material imported for consumption decreased 42 percent. The decline in the amount of available domestic antimony was due largely to curtailment of output of tetrahydrite ores in Idaho and reduced activity at Alaskan mines. Lack of ships, decrease in price, and tightening of grade specifications for Bolivian ores combined to reduce imports of South American ores by more than 10,000 tons of contained antimony. The antimony content of antimonial lead produced from all classes of foreign and domestic ore increased 37 percent, and recovery from scrap increased 40 percent. Industry-owned stocks increased slightly, but total inventories, including those of Metals Reserve Company in the United States, decreased 25 percent.

The price of American antimony metal in less than carlots remained 15.84 cents a pound throughout the year. This compares with an average price of 15.92 cents a pound in 1943, 15.55 cents in 1942, and 14.00 cents in 1941 and 1940. The prices for antimony ores and concentrates remained unchanged throughout the year. The 50- to 55-percent ores were quoted at \$2.10 to \$2.20 per short-ton unit of contained antimony at New York.

Figure 1 shows trends in world production from 1910 to 1938 and United States imports and prices from 1910 to 1944.

POSTWAR OUTLOOK

Consumption.—The expectation is that consumption of metallic antimony and antimony oxide for some time after the war will be higher than the prewar rate.

Demand for passenger automobiles and for industrial and farm vehicles and power units, with their accompanying requirements for

battery and bearing metals, will be tremendous. The use of antimony in alloys for manufacturing ornamental castings, collapsible tubes, and foil at least will return to normal after restrictions are no longer necessary.

Consumption of antimony oxide in the production of flameproofed textiles and fire-retardant paints will diminish with the inevitable decrease in military demand. However, these uses for the civilian market, now that war-born necessity has proved their efficacy, are expected to be high, with a consequent over-all increase in consumption of oxide above the prewar level. The successful application of flameproofing compounds to military textiles may well point the way to their use on such commonplace things as household draperies and awnings, theater curtains, and commercial tentage and tarpaulins.

Production.—The outlook for domestic mine production of antimony ores and concentrates is not good. That for smelter production of antimony metal and oxide is contingent upon the success of Chinese metal in recapturing its former large share of the United States market.

As 95 percent of the antimony contained in domestic ores produced during 1944 came from four Idaho mines operated primarily for lead, silver, tungsten, or copper and only 3 percent came from mines operated solely for antimony, future production obviously will continue to be largely as a byproduct and to depend on the output of other metals. Production of antimony metal from antimony ores can be expected if a high price, caused either by sustained demand or Government subsidy, is maintained, but such production—if past records are any criterion—will be relatively negligible. Only high prices for the metals with which antimony is associated in other deposits will keep operators such as Bradley Mining Co., Sunshine Mining Co., and Coeur d'Alene Mines Corp. in antimony production.

Imports.—Imports will continue to supply most of the domestic requirements of antimony, but the origin of these imports is conjectural.

Bolivian operators will continue to mine and export ore as long as the price is high enough for the controlling dealers to make a profit, and some of this ore will find its way to the United States. Similarly, Mexican output will continue, and most of it undoubtedly will be shipped to the United States as refined metal and contained in ore and antimonial lead. Receipts of antimony from both countries will depend to some extent on competition from European buyers.

Reestablishment of peace in China certainly would have a profound effect on world trade in antimony. Production in that country has been disrupted for more than a decade due to war. During the 5-year period 1930–34 United States imports of antimony metal and antimony contained in ore averaged 6,400 tons a year, 3,500 tons or 55 percent of which was Chinese metal. Chinese antimony resources are adequate to support a production much greater than has been made at any time in the past. Moreover, the certain need for United States credits points to the offering of Chinese antimony at competitive prices below those domestic producers are likely to be able to meet.

DOMESTIC MINE PRODUCTION

Only 11 antimony-producing mines reported any output in 1944 compared with 17 in 1943 and 31 in 1942. Production of ore and concentrates dropped 20 percent to 13,501 tons, the 4,735 tons of contained

metal being 15 percent lower than the comparable total for 1943. The Yellow Pine mine of the Bradley Mining Co., Valley County, Idaho, produced 91 percent of the antimony contained in domestic ores and concentrates. Only 140 tons or 3 percent of the antimony content of all ores and concentrates produced was from straight antimony ores, the remainder being contained in ores valued chiefly for their content of other metals.

Alaska.—Only one mine in Alaska is known to have produced antimony ore during 1944. Ernest Maurer shipped 73 tons of 48-percent ore from his Slate Creek mine in the Kantishna district to the Metals Reserve Company stock pile at Fairbanks. No report was received from Earl Pilgrim regarding operations at the Stampede mine, also in the Kantishna district. According to the Geological Survey, operations at this mine ceased early in 1944.

California.—On the basis of reports to the Bureau of Mines and Metals Reserve Company purchase records, it is estimated that approximately 15 tons of ore containing 5 tons of antimony were produced from three mines in Inyo, Kern, and Riverside Counties.

Idaho.—The mines of Shoshone and Valley Counties continued to yield most of the antimony obtained from domestic sources. The Yellow Pine mine of the Bradley Mining Co. and the Mineral Point mine of the Coeur d'Alene Mines Corp. were by far the most important. The Sunshine Mining Co. closed its electrolytic antimony plant in March 1944. Production from the Sunshine mine dropped nearly 95 percent for the year as the company directed its entire attention from the "dry-belt" silver ores to the newly developed silver-lead ores of the Chester vein.

Nevada.—Antimony mining in Nevada decreased slightly during 1944; three operators produced 74 tons of ore containing 30 tons of metal.

In November 1944 the Metals Reserve Company announced that purchase depots at Battle Mountain and Winnemucca would cease to receive antimony ores after December 31, 1944.

Oregon.—According to a recent report¹ there are five mines in Oregon of which there is a record of production. These are the Gray Eagle (formerly the Koehler), the Coyote, the Stibnite (also known as the Parker), the Jay Bird, and the Lowry. There are also at least seven prospects from which no production has been recorded. The Gray Eagle and the Jay Bird mines were the only known producers of antimony ore during 1944.

The Gray Eagle mine in Baker County, owned and operated by Anthony Brandenthaler, yielded 1,170 tons of low-grade antimony-gold ore, which was shipped to the U. S. Smelting, Refining & Mining Co. plant at Midvale, Utah, and 78 tons of high-grade antimony ore, which was shipped to the Metals Reserve Company depot, Seneca, Oreg. This mine was first worked in 1907, and small shipments have been made at infrequent intervals since that time. The preparation of the ore for shipment consists of dumping the mine-run ore on a grizzly with half-inch openings. The oversize is hand-sorted to obtain antimony ore, and the undersize is shipped as antimony-gold ore. Most of the antimony is present in the oxide minerals stibiconite and cervantite.

¹Wagner, Norman S., Antimony in Oregon: Oregon Dept. Geol. and Mineral Industries, G. M. I. Short Paper 12, 1944, 20 pp.

The Jay Bird mine in Jackson County was discovered in 1939 and was acquired by its present owners, S. J. and E. P. Merrick, in 1941. Under the Merrick brothers the mine has yielded approximately 125 tons of ore containing about 47 percent antimony. The dominant mineral is the sulfide stibnite, but some kermesite—the oxysulfide—is mined. During 1944 the ore was hand sorted and shipped to the Metals Reserve Company stock pile at Grant's Pass, Oreg.

Utah.—The Dry Lake Mining Co., with property in Hunsaker Canyon, Box Elder County, was again the only producer of antimony ore in Utah.

CONSUMPTION AND PRODUCTION BY SMELTERS AND MANUFACTURERS

Primary antimony raw materials (including various types of ores and concentrates) were consumed by producers of the intermediate products antimony metal, oxide, and sulfide and by manufacturers of finished metallic and nonmetallic products. Together these two groups used 22,675 tons of antimony contained in ores and concentrates during the year—a 4-percent decrease from the 1943 figure. Only 45 percent of the total consumed was from mixed or oxide ore—mostly from Mexico—as compared with 56 percent in 1943. A sharp decrease in consumption of tetraedrite concentrates came as a result of the Sunshine Mining Co. shift from mining “dry-belt” ores to the silver-lead ores of the Chester vein.

¹ Revised figures.

Smelter production.—Nine plants consumed 22,000 tons of antimony in raw materials, including 19,000 tons in ores and concentrates, and produced antimony metal, oxide, and sulfide containing 20,000 tons of antimony, slightly less than the 1943 output. The Bureau of Mines is not at liberty to publish separate figures on the output of these three intermediate primary products. Antimony metal was produced at five plants in the United States during the year, oxide was manufactured at seven plants, and sulfide at three plants.

The Texas Mining & Smelting Co., Laredo, Tex., continued to depend mainly on mixed and oxide ores from Mexico but also used some domestic sulfide ores and Bradley Mining Co. (Yellow Pine mine) concentrates to make antimony metal and oxide. The Sunshine Mining Co. closed its electrolytic plant in March 1944. The electrolytic plant of Bunker Hill & Sullivan Mining & Concentrating Co. was operated throughout the year on stibnite concentrates from the Yellow Pine area. The Harshaw Chemical Co. produced metal and

oxide at its El Segundo (Calif.) plant, oxide at Elyria, Ohio, and sulfide at Philadelphia. The American Smelting & Refining Co. produced metal and oxide at Omaha and oxide at Perth Amboy. The McGean Chemical Co. made oxide and sulfide at Cleveland, Metal & Thermit Corp. made oxide at Carteret, and Rare Metal Products Co. made sulfide at Belleville, N. J.

Production by manufacturers.—In 1944, antimony ores and concentrates and antimony metal, oxide, and sulfides containing 23,756 tons of antimony were consumed at 400 plants in the production of the metal and nonmetal products listed in the following table.

Industrial consumption of primary antimony, 1943-44, in short tons

[Antimony content of raw materials, including ores and concentrates, metal, oxide, and sulfides, put in process]

Product	Antimony consumed in the manufacture of products listed	
	1943	1944
Metal products:		
Antimonial lead.....	2,889	5,287
Bearing metal and bearings.....	1,563	2,637
Battery metal and battery parts.....	2,400	2,341

Matches.....	18	10
Other.....	385	333
Total nonmetal products.....	10,329	11,509
Grand total.....	19,508	23,756

Use of antimony in the production of all the major metal and non-metal products listed except battery metal and battery parts and flameproofed textiles increased sharply. The use of antimony oxide in flameproofing compounds for application to cotton duck, web belting, camouflage nets, and similar products and in fire-retardant and other paints accounted for 61 percent of the antimony used in the manufacture of nonmetal products and 30 percent of the total consumed for making all commodities.

Primary lead smelters produced 57,902 tons of antimonial lead containing 4,670 tons (8.1 percent) of antimony. The probable reason for the gain in antimony content from 5.3 percent in 1943 is the cut-back in small arms ammunition production in 1944 and consequent less demand for the lower-percentage antimonial lead used for bullet core rod. Of the total 1944 tonnage produced, 43

percent of the contained antimony was derived from domestic ores, 18 percent from foreign ores, and 39 percent from scrap. Details are presented in the accompanying table.

Antimonial lead produced at primary lead refineries, 1940-44, in short tons

Year	Production	Antimony content				
		From domestic ores ¹	From foreign ores ²	From scrap	Total	
					Quantity	Percent
1940.....	29,762	1,915	162	867	2,944	9.9
1941.....	40,237	2,586	372	552	3,510	8.7
1942.....	51,762	2,396	871	257	3,524	6.8

1944.....	57,902	2,015	842	1,813	4,670	8.1

¹ Includes primary residues and small quantity of antimony ore.

² Includes foreign base bullion and small quantity of foreign antimony ore.

³ Revised figure.

STOCKS

Combined producer and consumer inventories of antimony metal and of antimony in ores and concentrates, oxide, and sulfide increased slightly from 8,089 tons on December 31, 1943, to 8,165 tons on December 31, 1944. In addition to the above, there were mine stocks of 5,114 tons in domestic ores and concentrates. The supply of raw materials available from these two sources for the manufacture of finished products was therefore 13,279 tons (antimony content), or 11 percent more than the 11,915 tons available at the end of 1943, excluding Metals Reserve Company stocks.

SECONDARY PRODUCTION

The Minerals Yearbook chapter on Secondary Metals—Nonferrous presents a detailed review of the secondary antimony industry. The combined recovery of secondary and primary antimony during 1944 amounted to 39,642 tons, of which 15,886 tons or 40 percent was from secondary sources. Old battery lead plates continued to supply the bulk of the secondary antimony.

PRICES

The price of domestic brands of antimony metal, 99.5 percent minimum, in less than carlots remained at 15.84 cents a pound and of Chinese brands (duty paid) at 16.50 cents a pound (nominal), throughout the year. The price of domestic metal in bulk, f. o. b. Laredo, Tex., remained 14.50 cents. The London price for metal, 99 percent minimum, remained £120 a ton until January 1, 1945, when the official price was lowered to £105.

Quotations for antimony ores and concentrates, according to E&MJ Metal and Mineral Markets, remained throughout the year \$2.10 @ \$2.20 a short-ton unit for the 50- to 55-percent grade; \$2.15 @ \$2.20 for 58 to 60 percent; and \$2.20 @ \$2.30 for 60 to 65 percent. The London price at the beginning of the year was 12s. 6d. a long-ton unit. About the middle of the year this dropped to 12s. then to 11s. 6d., and closed at 11s.

Average monthly quoted prices of antimony, prompt delivery at New York, 1940-44, in cents per pound, for less than carlots

WAR AGENCY REGULATIONS

Antimony was removed from allocation control by an amendment to War Production Board General Preference Order M-112 dated December 4, 1943, effective January 1, 1944, and remained on the "free" list throughout the year. Consumers were still required to report to the Board, but the reports were to be filed quarterly instead of monthly. Toward the end of the year demand increased to the extent that the necessity for resumption of control became apparent. Accordingly, on February 3, 1945, the order was amended, effective February 10, requiring monthly reports and applications for allocation of antimony in its various forms. This amendment required any firm that had in its possession on the first of any calendar month, or that had used during the previous month, 2,240 pounds or more of antimony contained in ore or in any alloy or compound, to submit the required monthly report of activities.

Demand, particularly for antimony oxide, continued to exceed supply and producing capacity, and on March 14, 1945, General Preference Order M-112 was amended further to include possessors or consumers of 224 pounds of contained antimony.

FOREIGN TRADE ²

Detailed information on the imports and exports of antimony materials are presented in the following tables.

Antimony imported for consumption in the United States, 1940-44

¹ Less than 1 ton.

Although domestic production of antimony ores has been increasing during recent years, the United States still depends on imports of foreign ores for its supply.

Most of the ores—which come from Mexico—are of the mixed or oxide type containing 30 to 35 percent antimony. During 1944 Mexico furnished 11,087 tons of antimony contained in ores and 220 tons of metal.

Bolivia has been our second most important source of antimony contained in ores and our most important source of high-grade ores. The types imported are chemical grade, for oxide production, and metallurgical grade, suitable for the production of metal or alloys.

Imports of 752 tons of metal contained in ore and 74 tons of metal were credited from Peru in 1944. The records show small quantities of ore imported from Chile, but probably this was mined in Bolivia or Peru and shipped from a Chilean port. Imports from China have been cut off since 1941, during which year 7,115 tons of metal were received from that country.

Exports of domestic antimony materials in 1944 amounted to 1,319 short tons (gross weight), including 574 tons of antimony compounds, 696 tons of metal and alloys, and 49 tons of ores and concentrates.

Reexports of foreign materials included 604 tons of ores and concentrates (gross weight) and 18 tons of metal and alloys.

WORLD PRODUCTION

Many war-period data on the antimony industry of the world, previously concealed, became available during 1944. Reports were received for the first time in recent years from Portugal, Spain, Morocco, and China, as well as official production figures for several other countries. It is still impossible, however, to arrive at a reasonably accurate figure on total world production for any year later than 1938.

¹ Approximate recoverable metal content of ore produced exclusive of antimonial lead ores. 92 percent of reported gross content is used as basis for calculations in nearly every instance. Chosen and Japan produce antimony, but data on production are not available.

² Estimate.

³ Data not available.

⁴ Includes antimony content of antimonial lead.

⁵ Figures represent antimony content of regulus, crude antimony, and oxide exported.

⁶ Production of Free China.

⁷ Exports.

⁸ January to June, inclusive.

REVIEW BY COUNTRIES

Algeria.—Ores from the Ain Kerma and Kheneg mines in Algeria have been the French smelting industry's principal source of supply in recent years, but these deposits are said to be rapidly nearing exhaustion. Recorded production dropped from 478 metric tons of estimated recoverable metal in 1941 to 184 tons in 1943, the latest year for which figures are available.

Argentina.—The relatively small requirements for antimony in Argentina are usually met by production from mines in the Department of Rinconada, Province of Jujuy, supplemented by imports from Bolivia. To encourage the domestic metallurgic industry, antimony ore imported for the production of metallic antimony was declared free of import duties by Executive Decree 22,813, dated August 25, 1944.

Belgium.—Mr. Charles Gitlan, New York, informed the author in May 1945 that the plant of the Campine of Belgium, Antwerp, was not damaged during the German occupation and was but slightly damaged during the liberation. The works have been repaired, and the company is now seeking antimony ores for the production of antimony metal, oxide, and alloys.

Bolivia.—A recent press dispatch ^a from La Paz states that Banco Minero has announced an increase in prices for antimony ores and will accept ores of lower grade and increased allowable impurities. For more than a year Banco Minero would not buy ore containing less than 60 percent antimony or more than 0.5 percent of lead and arsenic combined. This restriction on grade imposed by one of the country's largest dealers in antimony, plus a shortage of ships, caused production and exports to decrease 58 percent to 6,852 metric tons of recoverable metal, the lowest since 1937.

Canada.—The Consolidated Mining & Smelting Co., Trail, British Columbia, was the principal producer of metallic antimony in 1944. The metal is recovered electrolytically as a byproduct from smelting operations on complex ores. Production for the year increased 75 percent to 817 metric tons of recoverable metal. Canadian consumption apparently is much greater than this production, for in mid-1944 the Canadian Metals Controller, Department of Munitions and Supply, granted some consumers permission to import American antimony at a considerable increase over the official Canadian ceiling price. In April 1945 the Metals Controller reinstated restrictions on the sale of antimony, including antimonial lead containing 25 percent or more of antimony, and required that all persons possessing the metal or its alloys report each month on inventory, consumption, receipts, and shipments.

China.—Chinese reserves of antimony ores probably are larger than those of any other country. The following table, compiled in 1941 by the Chinese Government Ministry of Economic Affairs, gives estimates of these reserves by Provinces. Only ores that can be recovered by current primitive mining methods are included. No data as to the grade of the ores were given.

^a American Metal Market, May 18, 1945.

During the 10-year period from 1931 to 1940, China produced 116,674 metric tons of antimony metal, 14,914 tons of liquated sulfide, and 7,177 tons of oxide. Of these totals the mines of Hunan Province yielded 95.6 percent of the metal, 98.8 percent of the sulfide, and all of the oxide. Changsha, capital of Hunan and center of the Chinese antimony industry, was captured by the Japanese in June 1944. A year later Chinese troops with American support were driving the Japanese out of the Province. Owing to the war antimony production in Free China dropped from 3,510 metric tons in 1942 to 428 tons in 1943 and 203 in 1944. In 1942, 17 tons of antimony metal were exported to the United States and 71 tons to Russia. There were no exports in 1943 or 1944.

China has never consumed more than an insignificant quantity of antimony—100 to 200 tons a year being used to manufacture matches, firecrackers, and enamel. Recently, however, the Chinese Government has established a factory for the manufacture of pigments in an effort to increase domestic consumption and a refinery for making higher-grade metal in a bid for foreign trade.

At the Chinese Government Industrial and Mining Exhibition in 1944, antimony white, antimony red, antimony yellow, antimony blue, and enamels were exhibited. The old classification for No. 1 Chinese antimony was a minimum of 99 percent antimony and a maximum of 0.3 percent arsenic. The newly established grades of refined metal are: (1) 99.8 percent antimony, minimum, and 0.1 percent arsenic, maximum; (2) 99.6 percent antimony, minimum, and 0.2 percent arsenic, maximum; (3) 99.0 percent antimony, minimum, and 0.25 percent arsenic, maximum. These higher grades are produced by oxidation with compressed air, using soda ash as a dearsenizer.

According to the Central Planning Board of the Supreme National Defense Council of China, as reported by the Foreign Commerce Weekly (United States), production of metallic antimony in the first

postwar year is expected to be 3,000 metric tons, increasing to 15,000 tons by the fifth year. Domestic consumption is expected to increase from an estimated 500 tons in the first postwar year to as high as 1,000 tons annually, leaving 2,500 to 14,000 tons available for export.

France.—Past French production has come from stibnite deposits near Lucette, in the Department of Nayenne, where a small smelter was operated before the war, and from Cuche, in the border region of Cantal and Haute-Loire, where the reopened Doze mine is producing 15 to 20 tons of concentrates a month.

This year, for the first time since 1934, France appears in the table of world production of antimony from domestic ores. From 1935 to 1941, inclusive, there is no record of any output of the metal from French mines, but smelter output from imported ores continued. During the war years 1940–44 average annual smelter production was 673 tons, largely from Algerian ores. Production from domestic ores was 128 metric tons of estimated recoverable metal in 1942, 153 tons in 1943, and 107 tons in 1944.

Greece.—Undeveloped deposits of antimony minerals have been reported on the islands of Mytilene, Lesbos, and Thassos; in the Othyrus Mountains; and in the hills north of the Gulf of Volo. Some production is known to have been made from the Antoniadès mine near Golgothas in the Department of Serres, Macedonia, and French-owned mines near Keram, on Chios Island.

Honduras.—Small quantities of ore have been exported in recent years from deposits in the Departments of Copan and Olancho. The highest recorded production was in 1943, when 110 metric tons of recoverable metal were exported.

India.—Small deposits of antimony in Chitral and Lahaul (Spiti) have been worked when the price was high but their potential output is insignificant compared with the demand from India's modern industry.

Iran (Persia).—A small but unrecorded output of antimony is made from deposits at Anarak, about 200 miles southeast of Tehran, and at Firdaus (Tourn), about 400 miles east of Tehran. Ore from Anarak is smelted locally, and that from Firdaus is shipped to a smelter at Tehran.

Italy.—Italian production of antimony comes from the islands of Sardinia and Sicily and from deposits in northern Italy. Smelters are located at Vallacides, Sardinia, and Rosia, northern Italy.

Morocco, French.—Small reserves of antimony associated with lead are known to exist in veins in carboniferous schists at Gouard ou Fellous and Tafoudeit. Potential production from these deposits has been estimated at 150 tons of 60-percent concentrates a month, but recorded production from the entire country during the 5-year period 1940–44 averaged only 277 metric tons of recoverable antimony contained in ores and concentrates a year.

Morocco, Spanish.—A small quantity of antimony ore has been shipped to Spanish smelters each year, but this production is decreasing owing to competition from deposits being developed in Spain.

Peru.—The Cerro de Pasco Copper Corp. is the largest producer of antimony in Peru. This output enters trade in the form of bars containing 95 percent antimony. Nearly 100 small operators ship hand-sorted ore from deposits in the Departments of Ancash, Huancaavelica, Huanuco, Junin, La Libertad, Lima, and Puno. Production

decreased 63 percent from 2,472 metric tons of recoverable metal contained in ores and concentrates in 1943 to 914 metric tons in 1944.

Spain.—Normal annual consumption of antimony metal in Spain is 150 to 200 metric tons, and production during the 5-year period 1940-44 averaged 370 tons. This production came mainly from mines at Almuradiel, Ciudad Real Province, and the Villarbacu mines, Lugo Province, although some ore is mined in Coruña, Gerona, and Orense Provinces.

Turkey.—Deposits of stibnite are known near Aydian, in the western part of the country, and Turhal, about 175 miles northeast of Ankara, but as far as is known there was no output during 1944. Production of ore averaged 1,100 metric tons a year from 1936 to 1939 but was of little significance in 1940 and 1941. In 1942, however, 1,449 metric tons were mined and shipped to Germany. Measured reserves of ore at Turhal are reported to be 70,000 metric tons.

Union of South Africa.—More than 5,000 tons of antimony concentrates were produced from gold ores in the Leydsdorp area near Gravelotte station, northern Transvaal, during the fiscal year ended August 30, 1944.

United Kingdom.—No antimony ore is mined in Great Britain or Northern Ireland, but smelter production from imported ores and concentrates gives the United Kingdom an important place in world trade in the metal and its compounds. The antimony supply situation apparently is somewhat better in England than in the United States because all restrictions on buying and selling antimony metal, sulfide, and oxide were lifted, effective February 8, 1945.

Yugoslavia.—Antimony deposits are known in Serbia, Bosnia, and Slovenia, but only those of Serbia are mined. From 1938 through 1940—the last year for which data are available—Yugoslavia was the world's fourth largest producer of antimony.

A recent summary⁴ containing the latest available information is reprinted herewith.

The Stolica mine at Brzitza, 3 miles north of Krupanj, has been in the past the principal producer of antimony in the country. Before the war the mine was owned by Podrinje Mines, Ltd., an English company. The mine, the reserves of which are estimated to be sufficient for a minimum of 10 years at the present rate of mining, produced in 1938 about 12,000 tons of 17-percent antimony ore. The ore is transported by oxcart to the company antimony smelter at Krupanj. This smelter, which had an annual capacity to produce 1,500 tons of antimony metal, was enlarged and modernized in 1938 and its capacity increased to 1,800 tons.

In recent years, the Montania A. G., a German concern, has developed the Zajaca mine about 9 miles northwest of Krupanj and has installed at Loznica a smelter equipped with a Wallis furnace having a monthly capacity of 100 tons of antimony. Reports indicate that 3 to 4 tons of metal are being produced daily.

Four miles northeast of Ivanijica and about 25 miles southwest of Kraljevo is the Lisanski mine, which according to reports has been acquired by German interests. The ore reserves were found large enough to warrant the erection of a smelter capable of producing 900 tons of antimony per year.

⁴ Bureau of Mines, Foreign Minerals Survey: Vol. 1, No. 6, June 1944, pp. 11-12.

CADMIUM

By THOMAS P. WOOTTON AND FRANCES E. CREWS

SUMMARY

Cadmium continued to rank high among the critical materials throughout 1944, and close control was maintained by the War Production Board through General Preference Order M-65. Although both production and imports were greater than in 1943, increased military requirements and larger exports caused a net decline in stocks. A new cadmium plant, at the Eagle-Picher Co., Galena, Kans., lead smelter, came into production during the year. The stepped-up rocket program, plus the continued need for cadmium in tank and aircraft parts, precluded any increase in civilian supply. The Office of Price Administration ceiling price remained 90 cents a pound for commercial sticks and 95 cents for patented shapes.

¹ Revised figure.

DOMESTIC PRODUCTION

Cadmium is essentially a byproduct derived from residues accumulated in the recovery of other metals, and its production is related closely to that of other metals, notably zinc and lead.

In 1944, the sixth successive year of an uninterrupted upward trend, production of primary cadmium exceeded that of the previous year by 4 percent. The increase in production during the war period resulted not only from greatly expanded domestic needs—principally military—but also from the dislocation of the European zinc-smelting industry by the German invasion and occupation of the Low Countries. Zinc concentrates from the Belgian Congo usually went to Belgium for treatment, and in peacetime a large part of the zinc ore from eastern Canada, Australia, South America, and even Mexico was

shipped to European smelters for treatment. To handle this increased smelting burden, domestic capacity has been repeatedly enlarged, and one completely new plant was erected—the American Smelting & Refining Co. refinery at Corpus Christi, Tex. Domestic production of cadmium during the first years of the war was enhanced substantially by treatment of accumulated cadmium-bearing flue dusts, but most of those stocks have been exhausted, and at present most of the output is from current smelting of domestic and imported cadmium-bearing zinc and lead ores.

¹ Excludes compounds made from metal.

² Bureau of Mines not at liberty to publish figures separately for secondary cadmium compounds.

Of the 1944 output 63 percent came from 4 plants in 4 Western States, 30 percent from 11 plants in 7 Central States, and 7 percent from 6 plants in 3 Eastern States. Forty-three percent of the primary metallic cadmium was recovered at electrolytic zinc plants. All electrolytic zinc plants in the United States produce electrolytic cadmium except the Monsanto plant of the American Zinc Co. of Illinois, the residues from which are sent to Fairmont, Ill., for distillation. The Eagle-Picher Co. began production of cadmium at its Galena, Kans., lead smelter and pigment plant in March 1944. This plant derives its cadmium from lead fumes rich in cadmium and from baghouse fumes arising from the roasting of zinc concentrates for sulfuric acid manufacture. This material is treated in leaching and precipitating tanks and a Faber du Faure distilling furnace. The final metal is cast into bars for the market.

A large quantity of the cadmium-compound output is from metal, but some is produced directly from primary residues and secondary metal. Production in 1944 was 39 percent greater than in 1943. In the accompanying table figures on certain compounds are grouped to avoid disclosure of confidential information.

Cadmium compounds produced in the United States, 1942-44, in pounds

¹ Includes cadmium lithopone and cadmium sulfoselenide.² In addition to quantities shown, cadmium oxide consumed in making other compounds shown was produced as follows: 1942, 38,721 pounds (Cd content, 33,881 pounds); 1943, 25,975 pounds (Cd content, 22,833 pounds); 1944, 31,469 pounds (Cd content, 27,662).³ Bromide included with hydrate to avoid disclosure of confidential figures.⁴ Iodide included with hydrate to avoid disclosure of confidential figures.FOREIGN TRADE ¹

Total 1944 imports of metallic cadmium and of cadmium contained in flue dust increased 10 percent, and total exports of cadmium metal and cadmium contained in compounds increased 176 percent.

Imports.—Cadmium contained in imported flue dust, all of which came from Mexico, increased 3 percent from 1,643,404 to 1,689,322 pounds, and imports of metallic cadmium increased 36 percent from 48,891 to 66,627 pounds. Imports of metal originated in the Belgian Congo, Italy, and Peru. The receipt of 8,656 pounds of cadmium from Italy in 1944 marked the first imports from that country since 1939, when 35,304 pounds were received. This metal was old stock confiscated by the Allies from a smelter on Sardinia. Imports from Peru began in 1943 but were lower by 43 percent in 1944.

¹ United Kingdom of Great Britain and Northern Ireland.

Exports.—During 1944 exports of metallic cadmium increased 196 percent from 153,637 to 454,644 pounds, and exports of cadmium contained in compounds decreased 20 percent from 15,628 to 12,558 pounds. Much of this large increase in foreign shipments was accounted for by shipments to Russia. Metal export figures are based

¹ Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

on returns from exporters to the Bureau of Mines, whereas those for compounds in 1944 and 1943 were estimated from data for gross weight obtained from the United States Department of Commerce. In addition to the exports mentioned above, the Commerce Department reported under cadmium exports the shipment to Mexico of 1,343 short tons of "lead-bearing flue dust," but the cadmium content was not given.

CONSUMPTION AND USES

Domestic consumption of cadmium increased 20 percent in 1944 compared with 1943, all of which can be attributed to larger military requirements. Total demand was so much greater than supply that additional stress was laid on use of substitutes, notably zinc. Representatives of the armed services reported to the War Production Board² that they had been able to divert 1,500,000 pounds annually to essential items by utilizing zinc for certain plate finishes.

Consumption of cadmium for electroplating declined 15 percent, but its use in bearings increased 220 percent over 1943. Use of cadmium in solders and other alloys decreased 27 percent and in chemicals and pigments increased 58 percent. Twenty-two percent of the total consumption was for unspecified uses.

Consumption of cadmium in the United States, 1941-44, by uses

Use	1941		1942		1943		1944	
	Pounds	Percent of total	Pounds	Percent of total	Pounds	Percent of total	Pounds	Percent of total
Electroplating.....	4,586,000	59	6,551,000	87	6,481,000	88	5,496,000	62
Bearings.....	1,504,000	19	282,000	4	249,000	3	798,000	9
Solders.....	130,000	2	201,000	3	285,000	4	266,000	3
Other alloys.....	221,000	3	98,000	1	198,000	2	89,000	1
Pigments.....	1,246,000	16	367,000	4	139,000	2	177,000	2
Chemicals.....	79,000	1	50,000	1	29,000	1	89,000	1
Other.....							1,950,000	22
Total.....	7,766,000	100	7,659,000	100	7,381,000	100	8,865,000	100

¹ Includes cadmium for unspecified uses.

Electroplating.—Sixty-two percent of the total United States consumption of cadmium during 1944 was for electroplating. Of this total 95 percent was for military use, mostly the manufacture of aircraft.

Alloys.—Bearings for heavy-duty use consumed 9 percent of the cadmium, solders 3 percent, and other alloys 1 percent. Cadmium is used in solders and fuse metals to lower the melting point.

Compounds.—Use of cadmium in compounds accounted for only 3 percent of the total consumption. The sulfide and sulfoselenide give yellow and red color to paints, inks, rubber, leather, and ceramic products; the oxide, hydrate, chloride, and fluoborate are used in electroplating solutions; and the halides are used in photography.

² Press Release, WFB-7127, Jan. 12, 1945.

STOCKS

Total domestic (including Government) stocks of cadmium on December 31, 1944, showed an 11-percent decrease from the 1943 figure. Stocks of cadmium compounds in the hands of producers and of distributors increased 187 and 72 percent, respectively. Details are given in the accompanying table.

Cadmium stocks at end of year, 1943-44, in pounds

	1943 ¹			1944		
	Metallic cadmium	Cadmium compounds (Cd content)	Total cadmium	Metallic cadmium	Cadmium compounds (Cd content)	Total cadmium
Producers	405,644	22,003	427,647	306,896	63,186	370,082
Compound manufacturers	29,930	91,780	121,710	11,558	63,267	74,825

¹ Revised figures.

² Comprises principally 6 largest dealers.

³ Partly estimated. Includes some material in process. Excludes stocks of compounds held by pigment and chemical consumers.

PRICES

Office of Price Administration ceiling prices of 90 cents a pound for metallic cadmium sticks and 95 cents a pound for patented shapes prevailed throughout the year. Value of shipments of the metal, as reported to the Bureau of Mines by primary producers, was 75 cents a pound in 1944 compared with 79 cents in 1943 and 1942 and 78 cents in 1941. Producers' quotations, according to E&MJ Metal and Mineral Markets, remained at 90 cents a pound.

Prices for cadmium compounds, as quoted by Oil, Paint and Drug Reporter, were \$1.65 to \$1.91 a pound for cadmium bromide, \$0.85 to \$1 for cadmium lithopone red, \$0.55 to \$0.65 for cadmium lithopone yellow, and \$1.10 for cadmium sulfide.

WORLD PRODUCTION

The following table shows available data for recent years on world production of metallic cadmium and United States production of metallic cadmium and cadmium compounds.

REVIEW BY COUNTRIES

Australia.—The Electrolytic Zinc Co. of Australasia, Ltd., reported the production of approximately 200 tons of cadmium from zinc concentrates and lead-furnace baghouse fumes. Prior to 1944 about 60 percent of this output was used by Australian industry, but beginning in 1944 more than half of it was exported to England.

Belgian Congo.—Thirteen metric tons of cadmium were produced during the year by "Sogechim", a subsidiary of Union Minière du Haut-Katanga, from zinc concentrates. This plant, a wartime installation, first reported production in 1941.

Canada.—Canadian output of cadmium comes from the Trail, British Columbia, plant of the Consolidated Mining & Smelting Co. of Canada, Ltd., and the Flin Flon, Manitoba, plant of the Hudson Bay Mining & Smelting Co., Ltd. Zinc ores from British Columbia furnished 75 percent of the metal, 22 percent came from Saskatchewan, and the remainder from Manitoba.

Italy.—More than 4 tons of metallic cadmium were imported into the United States from the electrolytic zinc plants on Sardinia, occupied by Allied forces in 1943.

Mexico.—Flue dust containing cadmium is recovered at the San Luis Potosí, Rosita, and Chihuahua smelters of the American Smelting & Refining Co. and at the Monterrey and Torreon smelters of the American Metal Co., Ltd., and shipped to the United States for refining.

Norway.—During prewar years Det Norske Zinkkompani annually produced about 150 tons of cadmium at its electrolytic zinc plant near Bergen, using zinc calcines from Belgium. In the first 5 months of 1944 the output was only 4 metric tons.

Peru.—Cadmium was produced by the Cerro de Pasco Copper Corp. at its Oroya smelter.

SUMMARY

Although there was no critical shortage of platinum metals in 1944, supplies of platinum, iridium, osmium, and rhodium were not adequate to permit their use for nonessential purposes.

Salient statistics of platinum and allied metals in the United States, 1943-44, in troy ounces

Refining of platinum in the United States was not only substantially less than in 1943, but it was insufficient for military and essential civilian requirements. The deficiency, however, was met by larger imports of refined metal and by the release of some Government stocks. Consumption (as measured by sales) of platinum declined 20 percent from the all-time record established in 1943. The drop was largely because in 1943 a substantial proportion of the platinum sold went into capital installations in the form of spinnerets for glass fiber and rayon and for laboratory ware. Despite the fact that in 1944 only 43,393 ounces of palladium were refined in the United States,

whereas domestic sales were 154,339 ounces, there was no problem in connection with supplies, because stocks were large. Both refining and sales of the other platinum metals—iridium, osmium, ruthenium, and rhodium—were comparatively small in 1944; nevertheless, refining of the first three of these metals did not equal demand. The deficit, however, was met by imports of refined metals. Enough rhodium was refined to fill demands.

In July 1944 the War Production Board freed iridium from direct allocation under Conservation Order M-49, but consumption remained limited to permitted uses. Larger supplies and reduced demand brought a price reduction in iridium in July from \$165 an ounce to \$120, where it remained the rest of 1944. Restrictions on the use of palladium in jewelry, as provided for in Order L-45 of WPB, were lifted in August.

Figure 1 shows graphically the trend in world production of platinum metals from 1914 to 1944.

FIGURE 1.—Trend in world production of platinum metals, 1914-44.

POSTWAR OUTLOOK

In appraising the postwar outlook for the platinum metals it is believed appropriate to review briefly the industry since 1930.

During the decade 1930-39 the world production of platinum metals increased from about 290,000 ounces in 1930 to 540,000 ounces in 1939. Concurrently, Canadian production of platinum metals advanced from 68,116 ounces to 284,304 ounces, as a result of the higher byprod-

uct output in Canada, where the platinum-group metals are found associated with the nickel-copper ores of the Sudbury district, Ontario. To absorb this greatly expanded output, research to find new uses was pursued with great energy and pronounced success, with the result that larger, more diversified markets were opened. Also, much attention was given to reviving old ways of utilizing the platinum metals. Meanwhile, the lower and more stable price of the platinum metals helped them to compete successfully with substitutes. As a consequence of these developments, consumption of the platinum metals has likewise increased phenomenally, and although exact information is not available it is believed that the bulk of the metals produced during 1930-39 was also marketed.

The war emphasized the importance and versatility of the platinum metals; accordingly, consumption has increased further. Despite prohibitions and limitations on the use of certain platinum metals for nonessential purposes, consumption (as measured by sales) in the United States advanced from 206,890 ounces in 1940 to 509,232 ounces in 1943. Much of this gain was due to the demand for platinum for electronic tubes, contact points, spark plugs, and catalysts.

Although a decline in domestic consumption of the platinum metals is expected with the ending of World War II, Englehard¹ believes that:

Much of what is being learned during the war concerning the uses and advantages of platinum metals will be applicable to post-war products and processes, which supports a confident view of the long-term possibilities of the platinum industry.

Although certain peacetime markets for platinum metals are necessarily restricted by their cost, the chemical, physical, and mechanical properties of these metals are so extraordinary that they are being used more and more for industrial purposes. Therefore, with stability in the price that will permit their continued use for industrial purposes, plus aggressive research to find further uses, it is believed that the platinum metals will expand steadily in their peacetime applications:

No new important deposits of platinum metals are known to have been discovered during recent years; consequently, future production will continue to come from established sources. Canada most certainly will maintain its predominant position as a producer, followed chiefly by the Union of Soviet Socialist Republics, Union of South Africa, Colombia, and Alaska, but not necessarily in that order.

Stable prices on platinum, palladium, rhodium, and ruthenium have prevailed for several years. As lower and stable quotations on the platinum-group metals have been an important factor in developing larger and more diversified markets, it is likely that most of the leading producers will favor a steady price policy. Nevertheless, when the restriction on the sale and use of platinum for jewelry and decorative use is removed by the War Production Board, it is possible, because of the accumulated demand for this metal by the jewelry trade, that there might be a short-lived price advance. No material price change is foreseen for palladium, osmium, rhodium, and ruthenium. Iridium, however, is more sensitive to supply and demand rumors and to speculation than any of the other platinum metals and as in the past probably will be subject to sporadic fluctuations in price.

¹ Englehard, Charles, *The Platinum Metals in 1944*: Am. Metal Market, vol. 82, No. 7, Jan. 11, 1945, p. 81

CRUDE PLATINUM

Production.—Mine returns for 1944 show a production of 33,616 ounces of crude platinum in Alaska and 9 ounces in Montana—a total of 33,625 ounces; comparable figures for 1943 are 27,100 ounces of crude platinum in Alaska and 62 ounces in California—a total of 27,162 ounces. Production in Alaska in 1944 came from placer deposits in the Goodnews Bay district of southwestern Alaska, which were mined by a large modern dredge and by well-mechanized draglines. The output in Montana was a byproduct of a dredge working a gold placer in the Missouri River district, Lewis and Clark County. There was no production of platinum in California and Oregon in 1944 because the gold dredges which formerly worked platinum-bearing gravels were idle under War Production Board Order L-208.

Many gold and copper ores in the United States contain small quantities of platinum metals. In 1944, 6,924 ounces of platinum metals were recovered as byproducts of refining gold and copper ores compared with 10,390 ounces in 1943.

Purchases.—Buyers in the United States reported purchases of domestic crude platinum from the following sources in 1944: Alaska, 33,457 ounces; California, 379 ounces; and Oregon, 5 ounces—a total of 33,841 ounces (28,130 ounces in 1943). Domestic buyers also reported purchases of 29,700 ounces (39,409 ounces in 1943) of foreign crude platinum from Colombia in 1944.

Prices.—Buyers reported purchases at \$26.25 to \$37.51 an ounce for domestic and foreign crude platinum in 1944. This price range resulted chiefly from variations in iridium content of crudes rather than from market fluctuations for refined platinum metals.

REFINED PLATINUM METALS

New metals recovered.—Reports from refiners of crude platinum, gold bullion, nickel, and copper indicate that 153,045 ounces of platinum metals were recovered in the United States from such sources in 1944—a decrease of 54 percent from 1943. Of the new metals recovered in 1944, 78 percent was chiefly from concentrates from Canada and crude from Colombia, 17 percent from domestic crude (chiefly from Alaska), and 5 percent a byproduct of domestic gold and copper ores.

Secondary metals recovered.—In 1944, 131,901 ounces of secondary platinum metals were recovered from the refining of scrap metal, sweeps, and other waste products of manufacture that contain platinum metals—a 30-percent increase over 1943.

Substantial quantities of worn-out catalysts, spinnerets, laboratory ware, and other products are returned by customers to refiners for refining. The refined platinum metals recovered from these products (or their equivalent in refined metals) are returned to the customers. The platinum metals so recovered are not included in the statistics of secondary metals.

1944.....	94,764	32,427	1,348	3,362	131,901

Prices.—Maximum prices for the six platinum metals, fixed by the Office of Price Administration on February 1, 1943, remained in effect in 1944. The maximum prices per troy ounce for refined metals of a commercial purity of at least 99.5 percent were as follows: Platinum, \$35; palladium, \$24; iridium, \$165; osmium, \$50; rhodium, \$125; and ruthenium, \$35.

Except for iridium, prices for the platinum-group metals remained stable in 1944. However, iridium, which was quoted at \$165 an ounce until July, was reduced to \$120, where it remained for the balance of 1944.

Properties and uses.—Much information on the platinum metals and their alloys, particularly their physical and mechanical properties and their many and diverse uses, is given in the comprehensive book, *The Platinum Metals and Their Alloys*, published in 1941 by the International Nickel Co., Inc., New York, N. Y. A tabulation of uses of the platinum metals is given in the chapter of this series for 1943.

Consumption.—As pure metals, combined, clad, or alloyed with other metals, the platinum metals are employed in the electrical and chemical industries, in dentistry and jewelry, and for numerous miscellaneous purposes. Sales to consumers in the United States were 452,204 ounces in 1944 compared with 509,232 ounces in 1943.

The most widely used metal of the group is platinum, which constituted 275,648 ounces (61 percent) of the total platinum metals sold to consumers in the United States in 1944. By taking 64 percent of the

total platinum sold, the electrical industry was again the chief buyer, but sales to it were 4 percent less than in 1943. The largest outlets for platinum in the electrical industry were for magneto and other contacts, electronic tubes, and spark plugs. Sales for contact points and electronic tubes were 24 and 34 percent, respectively, smaller than in 1943. However, sales of platinum for spark plugs—a new use—were 44,500 ounces in 1944. The chemical industry was the second-largest buyer of platinum in 1944, but its purchases were 54 percent less than in 1943. Nevertheless, it accounted for 60,936 ounces (22 percent) of the total sales. The decline was mainly because in 1943 a substantial amount of the platinum sold went into capital installations in the form of spinnerets for glass fiber and rayon and for laboratory ware. Sales of platinum for dental and medical uses again increased and accounted for 34,783 ounces (13 percent) of the total sold. Because of the ban on sale and use of platinum in the manufacture of jewelry, only 424 ounces were sold to the jewelry industry in 1944, presumably for repair work. Before World War II the jewelry industry absorbed over half of the platinum sold in the United States.

Next to platinum, palladium is the most extensively used metal of the group; it constituted 154,339 ounces (34 percent) of the total platinum metals sold to domestic consumers in 1944. The jewelry industry was again the largest outlet for palladium and took 56,558 ounces (37 percent) of the total palladium sold in 1944. Sales of palladium to the jewelry industry were 25 percent greater than in 1943. The electrical industry, which dropped from first to third place as a buyer of palladium in 1943, advanced to second place in 1944; it accounted for 42,322 ounces (27 percent) of the total sold. The dental trade was the third largest outlet for palladium in 1944, taking 36,377 ounces (24 percent) of the total sold. Sales of palladium to the chemical industry (9,673 ounces) were 32 percent less than in 1943. The pen and pencil trade became an important consumer of palladium for precious metal nibs and other parts in 1944.

The consumption of the other platinum metals—iridium, osmium, rhodium, and ruthenium—was comparatively small; it made up 5 percent (22,217 ounces) of the total for the group in 1944. Ruthenium and iridium were the most extensively used metals of this group, followed in order by rhodium and osmium. Sales of each of these metals were less than in 1943, but the decline for osmium was more pronounced than for the other metals.

The following table shows sales of platinum metals by refiners, importers, dealers, and Metals Reserve Company to consumers in the United States in 1944.

Platinum metals sold to consuming industries in the United States in 1944, in troy ounces

Industry	Platinum	Palladium	Iridium, osmium, rhodium, and ruthenium	Total

FOREIGN TRADE²

Imports.—After increasing for three successive years to establish a new record in 1943, imports of platinum metals declined slightly in 1944. The principal sources of imported platinum metals in 1944 were Canada (223,008 ounces), U. S. S. R. (75,322 ounces), Colombia (35,320 ounces), and United Kingdom (22,553 ounces). Imports of unrefined materials (137,192 ounces) were 48 percent less than in 1943, but imports of refined metals (219,020 ounces) were 123 percent more. Imports of refined platinum, palladium, and iridium were 70, 213, and 191 percent, respectively, greater than in 1943, but imports of ruthenium were 39 percent less.

¹ The concentrates and crude imported from Canada contain platinum, palladium, iridium, rhodium, and ruthenium, and the crude sponge imported from Canada contains platinum and palladium. Although the U. S. Department of Commerce records "platinum content" for these entries, the Bureau of Mines has determined from the importers of these materials that most of the entries reflect the platinum metals content. The Bureau of Mines has also determined from the largest importer of crude platinum from Colombia that the entries for his material, recorded as "platinum content" by the U. S. Department of Commerce, represent the gross weight of the material.

² Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

¹ Data not available.² Recovered from nickel-copper mattes.³ Year ended June 30 of year stated.⁴ Produced from platinum ores.⁵ January to June, inclusive.⁶ Produced from treatment of gold ores on the Rand.⁷ New platinum metals recovered in gold and copper refining of domestic materials.**REVIEW BY COUNTRIES**

Canada.—According to the Dominion Bureau of Statistics, production of platinum metals from the nickel-copper ores of the Sudbury district, plus an insignificant quantity from placers in British Columbia, was 155,700 ounces of platinum and 45,100 ounces of other platinum-group metals in 1944, compared with 219,713 ounces of platinum and 126,004 ounces of other platinum-group metals in 1943. Production of platinum metals in 1944 was the smallest since 1940. However, the decline in 1944 is more apparent than real, because the reported outputs represent the metals refined from Canadian concentrates at Acton, England, plus the platinum-metals content of concentrates sold, rather than the metals contained in the concentrates actually recovered.

Colombia.—Colombia exported 36,136 ounces of crude platinum in 1944 (39,961 in 1943). The South American Gold & Platinum Co. produced 22,615 ounces of crude platinum metals in 1944 (23,945 in 1943) and 56,097 ounces of crude gold (55,446 in 1943). The production figures for other operators are not available.

TITANIUM

GENERAL STATEMENT

Domestic titanium ore output in 1944 entered new high ground nearly 40 percent above the 1943 level. Ilmenite imports rose in the same ratio, but entries of rutile were lower. Consumption of ilmenite made another record, about 20 percent greater than the record of 1943 owing to capacity operation of pigment plants. The use of rutile, however, declined in keeping with the recession in welding-rod production, its principal use. Inventories of titanium concentrates increased nearly one-third during the year but barely kept pace with the expanding use rate. Prices of titanium ores and products remained unchanged.

Existent wartime use controls, principally relating to titanium dioxide, remained essentially unchanged. Military and other preferred uses took approximately 70 percent of pigment production and accounted for nearly 90 percent of rutile consumption.

The United States Department of Justice in June 1944 sought to enjoin the National Lead Co., its subsidiary, Titan Co., Inc., and E. I. DuPont de Nemours & Co. from continuing an international network of patent and marketing agreements that were stated to be in violation of the Sherman Antitrust Act.¹ The case was being tried in District Court for the Southern District of New York in March 1945.

POSTWAR OUTLOOK

The astonishing rate of growth in the over-all use of titanium (ores) in the past 2 decades probably will persist for several years. Roughly 90 percent of the titania used emerges in the form of pigments and most of the remainder as constructional and metallurgical materials. No substantial change in the use pattern is anticipated, although the order of importance of the last two named may be reversed. The supply of pigments has not met demand during the war despite existing plants operating at capacity; currently only about one-third of the production is available for civilian use or roughly one-half the immediate prewar quantity. There is thus a large ac-

¹ U. S. Department of Justice, Press Release: June 24, 1944. See also Titanium chapter, *Minerals Yearbook*, 1943, p. 807.

cumulated demand that represents deferred maintenance in the form of paints, floor coverings, coated textiles, and other materials that make up three-quarters or more of pigment use. Likewise, the construction of new buildings has been almost at a standstill. Direct and indirect military uses have absorbed two-thirds or more of available supply with the major part going to ships—naval and merchant. The construction of new vessels probably will cease abruptly, but the maintenance of the world's largest navy and a large merchant marine will require several times as much marine paint as heretofore. Consumption of titanium pigments in other fields has tended to increase in quantity, and it is believed that their relative share will not change notably. Furthermore, recent developments of improved types of titanium dioxide are expected to extend its usefulness as a white pigment.

As a constructional material titania has become nearly indispensable as a welding-rod coating. The output of titanium dioxide-coated rods more than trebled from 1941 to 1943 (the peak) as a result of the vast increase in welding in military construction and repair. Again, naval application predominated and is hence likely to be cut heavily. However, progress in the use of welding has been so great during the war that much of the gain will be translated to peacetime uses. Consumption of titanium in welding rods is likely, therefore, to fall off considerably but to remain well above the prewar level.

The situation in the metallurgical field is much the same as in that of construction. In general, titanium use will approximately parallel the steel-production trend. There is some likelihood, however, that it may have a steeper slope because of wartime developments in the production and use of ordinary and alloy steels and the cemented carbides.

On the whole, needs for titanium in the nearby future point toward a demand level higher than the present. More distantly there will be a leveling off, but probably requirements may remain near wartime levels.

The future of domestic production of titanium ores is less clear-cut. It is primarily related to the ability to obtain byproduct ilmenite at a cost comparable with that of higher-grade foreign material. Much of that production likewise hinges on the market for magnetite, the major component of the principal ores. At least to the end of the war production will be well maintained. Subsequently a sizable decline is probable, but total domestic output will hold well above prewar figures and for the long term may be expected to rise substantially.

DOMESTIC PRODUCTION

In 1944 production of ilmenite rose 37 percent above that of 1943, and output of rutile climbed 74 percent. All producers of ilmenite made substantial increases, whereas the great gain in rutile output resulted virtually from the operation of the Humphreys Gold Corp. Ilmenite concentrate shipments in 1944 contained 44 to 59 percent TiO_2 , and rutile concentrates 92 to 94 percent TiO_2 .

Arkansas.—The Magnet Cove Rutile Co., successor to Titanium Alloy Co. of Arkansas, at Malvern, Magnet Cove district, Hot Spring County, produced rutile concentrate in the first 7 months of 1944. A water shortage restricted mill operation. There has been some output in nearly every year since Arkansas production was first reported in 1932. Shipments of rutile (85–95 percent TiO_2) totaled 4,246 short tons to the end of 1943. A second grade (55–60 percent

TiO₂) had also been prepared but found no market. The ore contains 3 percent rutile on the average and 4 percent total TiO₂. Part of the titania, however, is locked up in magnetite or alteration products, and recovery is low. About 10 years ago the Bureau of Mines showed that a high-grade product could be made by flotation. Recent operations have been described.²

Production and mine shipments of titanium concentrates from domestic ores in the United States, 1940-44

Year	Ilmenite				Rutile

Florida.—The Humphreys Gold Corp., operating under lease from the Rutile Mining Co. of Florida and its parent company, the Titanium Alloy Manufacturing Co., produced rutile and ilmenite during 1944 from a 500-acre tract 8 miles east of Jacksonville. Between 4,000 and 5,000 short tons of ancient beach sand were treated daily; and monthly shipments of rutile and ilmenite totaled around 300 tons and 2,000 tons, respectively.³ Humphreys Gold Corp. moved its entire plant and equipment, formerly used in recovering chromite from ancient beach sands in Coos County, Oreg., to the Florida location and began operations there on April 1, 1944. This plant and operation have been described.⁴ Riz Mineral Co. produced ilmenite, rutile, and zircon concentrates from sands taken from dunes near Vero Beach, Indian River County. The concentrator is at Melbourne, Brevard County.

New York.—At Tahawus, New York, the National Lead Co. produced approximately 200,000 tons of ilmenite from about 1,000,000 tons of ore milled in 1944. All the ilmenite was shipped directly to pigment-producing plants.⁵ A magnetic cobber installed in the crushing plant rejects 10 to 20 percent of the crude ore as a tailing low in ilmenite and magnetite and thus increased the mill concentrate output. This and other minor operating improvements were the main factors contributing to the increase in 1944 over the 165,000 short tons produced in 1943. The manpower shortage continued and prevented attainment of the goal of 900 short tons of ilmenite concentrates daily—a goal set the year before to be reached by mid-1944.

North Carolina.—The Yadkin Valley Ilmenite Co., subsidiary of the Glidden Co., produced about 15,000 short tons of ilmenite at Finley, Caldwell County, in 1944, the concentrates averaging 49 percent TiO₂.

Virginia.—Rutile and ilmenite were produced near Roseland, Nelson County, by the American Rutile Corp., subsidiary of the Metal & Thermit Corp. The Virginia Chemical Corp., a producer of ilmenite in the same district, sold its chemical plant property in July 1944 to the Calco Chemical Division of the American Cyanamid Co. In March 1945 the mine and mill were taken over by the same company, so that now Calco Chemical Division, American Cyanamid Co., owns and operates the mine, mill, and chemical plant at Piney River, Nelson County.

FOREIGN TRADE ⁶

Imports.—The Allied successes in 1944 opened all sea routes and permitted India rapidly to expand ilmenite mining that had been dormant since Pearl Harbor; exports to the United States in 1944 were about seven times those of 1943. Brazilian imports were at a high point, and Ceylon appeared for the first time as a supplier. War-expanded imports from Canada were cut to half those of 1943 as other higher-grade ilmenite became available. Contraction in rutile requirements brought about a 30-percent decline in imports from the 1943 record. The 66-percent drop in Brazilian supply accounted for most of the change. At the same time imports from Australia slightly exceeded those of 1943 and made a new high because of the importation of a large volume of the mixed ilmenite-rutile-zircon concentrate that is the major source of zircon for which there was a strong demand.

¹ Classified as "ore" by the U. S. Department of Commerce.

² All imports of titanium from Australia in 1940-44 were in mixed zircon-rutile-ilmenite concentrates. Totals of mixed concentrates are derived by addition of the U. S. Department of Commerce figures for imports of ilmenite, rutile, and "zirconium ore" from Australia. These totals are divided by the Bureau of Mines (on the basis of surveys of importers) into the three component minerals. The excess quantities of ilmenite and rutile over the quantities reported by the U. S. Department of Commerce in those specific categories are entered as "In 'zirconium ore'."

³ Includes quantities reported by the U. S. Department of Commerce as originating in French Equatorial Africa, from which no rutile production has been recorded.

⁴ Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

in use of titanium dioxide mirrored changes in armament- and ship-construction programs and impending further cut-backs.

Titanium alloys.—The titanium ferro-alloys are important additives in the production of rimming and killed steels. The titanium-treated steels are cleaner, give higher ingot yield, and have generally better physical characteristics than untreated steels and some of those treated with other deoxidizers. In these applications there is little or no titanium residual in the finished steel. Titanium is also used as an alloying element, especially in stainless steels where its main effect is through carbide control to inhibit intergranular corrosion and embrittlement. A titanium alloy steel, now in commercial production, has made possible the direct application of white or light pastel vitreous enamels to steel without the use of a ground-coat enamel. This one-coat enameling steel possesses exceptional cold-drawing characteristics and resistance to sagging or bending at enamel firing temperatures and is reported not to age-strain.^{8,9}

Other uses.—Titanium tetrachloride was used as a screening smoke during the First World War and has been employed in substantial volume during the present conflict. At first it was usually prepared by chlorinating rutile in the presence of carbonaceous material. Subsequently and during the current war, titanium cyanonitride—an electric-furnace product—was reacted with chlorine to make the tetrachloride. These were high-temperature processes requiring careful controls, and the product was likely to be contaminated with impurities contained in the raw materials. Later, better results were obtained by substituting pigment titanium dioxide briquetted with finely ground charcoal and a binder in place of the cyanonitride.

PRICES

No price changes affected any form of titanium in 1944. Ilmenite and rutile prices were fixed by the Office of Price Administration February 22, 1943 (Regulation 327), at levels prevailing in March 1942. Ilmenite, 60 percent TiO_2 , was nominally quoted at \$28-\$30 a long ton, f. o. b. Atlantic seaboard, and rutile, 94 percent TiO_2 , at 8-10 cents a pound. Steel quoted ferrotitanium, ton lots, at \$1.23 per pound of contained Ti for 40- to 45-percent grade and \$1.35 for 20- to 25-percent grade; and ferrocabontitanium, 15-20 percent Ti, at \$142.50 a short ton for 6- to 8-percent carbon and \$157.50 for 3- to 5-percent carbon. Titanium metal, 96-98 percent, was listed at \$5-\$5.50 a pound. The base price of manufactured titanium dioxide remained fixed at $14\frac{1}{2}$ - $16\frac{1}{2}$ cents a pound.

TECHNOLOGY

The Bureau of Mines and Geological Survey made field studies on Wyoming titaniferous magnetite. The Bureau conducted laboratory research on metal and alloy production and on ore dressing of various raw materials.

The Humphreys spiral concentrator has efficiently separated heavy minerals from natural sands, with high recoveries. It is reported to be relatively insensitive to changes in pulp density and quantity and

⁸ Comstock, G. F., and Wainer, E., *New Titanium Steel for Vitreous Enameling*: Iron Age, vol. 155, No. 7, February 1945, pp. 60-63, 152-153.

grade of feed, and to particle size or shape. In the first commercial application—Oregon chromite-bearing beach sands—a concentration ratio of 2.25 : 1 was obtained, with a recovery of 98 percent.¹⁰ The Florida beach-sand spiral feed has 5½ to 11 percent heavy minerals. The concentrate ranges from 88 to 96 percent heavy minerals, mostly ilmenite and rutile, but was held close to 92 percent. Recovery exceeds 95 percent.¹¹

WORLD PRODUCTION

Data on world production of ilmenite and rutile in recent years are shown in the following table.

World production of titanium concentrates (ilmenite and rutile), 1937-44, by countries, in metric tons

¹ Data not available.

² Subject to revision.

³ January to November, inclusive.

⁴ Includes 26 tons of garnet-ilmenite.

⁵ Bureau of Mines not at liberty to publish figures.

⁶ In addition, zircon-rutile-ilmenite concentrates were produced as follows—1937: 73 tons; 1938: 98 tons.

⁷ Less than 1 ton.

⁸ Exports.

Australia.—Beach-sand deposits similar to those of New South Wales, which have been worked for a number of years, are being prospected and developed along 60 miles of potentially productive Queensland coast. Approximate mineral composition of the deposits, usually called "black sands," is as follows: Zircon, 40 to 45 percent; rutile, 30 to 35 percent; and ilmenite, 20 percent. The Minerals Deposits Syndicate in Queensland is now producing a high-grade monazite concentrate. The product from most of the plants is a mixed concentrate, but efforts are being made to produce clean concentrates of individual minerals, mainly rutile and zircon.¹²

¹¹ Humphreys, I. B., and Hubbard, Judson S., work cited in footnote 4, pp. 83-84.

¹² Engineering and Mining Journal, Queensland: Vol. 145, No. 10, October 1944, pp. 164, 165.

Brazil.—Brazil has the raw materials for the production of titanium oxide, and it is reported that the establishment of such an industry is being considered.¹⁵ There are large quantities of rutile in Ceara, Goiaz, and Minas Gerais. Brazil's deposits of ilmenite and monazite are found on the coast of Espirito Santo and Baía and are among Brazil's long-exploited minerals.

Ceylon.—Ilmenite is found in large quantities on the beaches of Ceylon. The Ceylon Government proposes to establish a plant for manufacturing paints in the island, using ilmenite as the principal pigment base.¹⁴

Egypt.—Ilmenite, zircon, and monazite are obtained in Egypt from black sand at the mouth of the Nile near Rosetta and Damietta. The minerals are extracted in plants at Rosetta and Alexandria.¹⁴

India.—Although the Travancore ilmenite deposits may be approaching exhaustion, other ilmenite-bearing sands are available along the east coast.¹⁶ Fairly large deposits of titaniferous iron ores occur in Mysore.¹⁷ Extensive deposits are also found in Singhbhum and Mayurbhanj which may develop into a future source of titanium.¹⁸

United Kingdom.—Official prices for rutile are unchanged at £54 a long ton for Cameroun concentrates, £42–£50 for Indian concentrates, and £45 for Australian concentrates. Indian ilmenite, 52–54 percent TiO_2 , is quoted at about 30s. per ton, f. a. s.¹⁹ Ferrotitanium price remained at £100 per long ton for the 2- to 3-percent carbon grade (20–25 percent Ti) and 1s. 3½d. per pound for the carbon-free grade.²⁰ Titanium pigment manufacturers in the United Kingdom have formed a Titanium Pigment Manufacturers' Specification Committee whose reported sole object is to assist in the preparation of official specifications involving titanium oxide.²¹

BARIUM AND STRONTIUM

The United States is believed to be the largest producer of barium and strontium and their aluminum or aluminum-magnesium alloys; output has been several thousand pounds annually. These metals and others, principally aluminum, calcium, magnesium, thorium, uranium, zirconium, and mischmetal (cerium and lanthanum mostly), are or have been used as "getters"¹ for the removal of residual gases and those evolved during service in all radio tubes and in virtually all other radionic tubes. Barium has been found to be the best all-round material, but it is ordinarily used in alloyed form. Barium-magnesium getter alloys contain 25-30 percent magnesium, barium-aluminum 50 percent barium, barium-aluminum-magnesium 1 part of the first to 3 parts of the second, and that containing strontium about 14 percent barium, 25 percent strontium, and the remainder magnesium. The getter materials are formed in tablets or pellets ranging in weight from about 2 to 40 milligrams, with the most commonly used sizes between 4 and 12 milligrams. The growth of the radio and radionic tube industry affords a measure of barium consumption. The dollar value of tube output in 1941 was 53 million; in 1942, 132 million; in 1943, 304 million; and in 1944, 406 million.

BERYLLIUM

The recession in demand for beryllium that became marked in the second half of 1943 continued in 1944 and resulted in a drop in consumption of one-fourth compared with 1943. Imports declined more than one-third as a result of contract cancellations but were still so much above current consumption that year-end stocks were equivalent to about 2½ years' requirements at the 1944 use rate. Allocation of beryllium under War Production Board Conservation Order M-160, was lifted August 19.

Domestic mine production.—Shipments from mines established a new record 9 percent above the preceding peak in 1943; however,

¹ A comprehensive review of production and application of getters is given in *Light Metals* (London) *Gettering and Getters*: Vol. 7, Nos. 72-73, January-February 1944, pp. 34-52, 77-94.

they covered less than one-fifth of domestic needs. Production expansion was largely a response to Metals Reserve Company increased buying price. The Bureau of Mines and Geological Survey examined beryl deposits in New England, the southern Appalachians, Black Hills, and Rocky Mountains. An unusual beryllium-bearing rock was described by Jahns,² and an occurrence of beryl associated with tantalum and lithium minerals was described by Jahns and Wright.³

Beryl crystals of great size are occasionally uncovered. The writer is indebted to Arthur F. Johnson, consulting mining engineer of Keystone, S. Dak., for the following information concerning those found on the property of the Black Hills Keystone Corp. In what is called the No. 2 Dike, one crystal mass that contained 24 tons of beryl was mined in 1933. Subsequently three others that provided 16, 11, and 6 tons of beryl, respectively, were excavated. In July 1942 a crystal 19 feet long was uncovered. At the small end it was 18 inches in cross section and at the other was slightly over 5 feet. This crystal weighed 34 tons. Not until November 1943 were any large crystals or masses found in the No. 1 Dike. Then, one mass without definite crystal form produced 26.5 tons. Late in 1944 a gigantic crystal was mined. The cross section was not determined; but the length was 28 feet, and it provided 61¼ tons of beryl. The Highland Lode mine near Custer, S. Dak., is also well-known as a source of large crystals. In 1940 one yielded 7 tons, and in April 1944 one of 5½-ton size was removed.⁴ Crystals weighing up to 1½ tons have been reported from Beryl Mountain near Keene, N. H.⁵

Foreign trade.—Withdrawal of United States Government support in foreign markets, especially in Argentina and Brazil, brought about a 37-percent drop in imports from the 1943 record level. British countries, however, furnished larger tonnages than in 1943. Exports were 19,065 pounds of ore, 84,229 pounds (\$68,090) of metal, alloys, and scrap, and 2,042 pounds (\$7,067) of salts and compounds.

¹ Less than 1 ton.

² 5 tons additional from Mozambique were reported to the Bureau of Mines.

Stocks.—Stocks in the hands of consumers and dealers were reduced to 131 tons from 1,036 at the beginning of the year. Miners disposed of their inventories in anticipation of a price drop after the termination of the Metals Reserve Company purchase program on December 31, 1944. That agency's small-lot purchase depots transferred their beryl stocks early in 1945 to stock piles in consuming areas near Reading, Pa., and Cleveland, Ohio.

Prices.—The Metals Reserve Company raised its buying price for domestic beryl from \$12 a short-ton unit of beryllium oxide to \$14.50, f. o. b. mine in May 1944 and maintained it at that level for the remainder of the year. Beryllium-copper master-alloy was quoted at \$15 a pound contained beryllium.

Uses.—The major use of beryllium is as an alloying element with copper, usually containing about 2 percent Be and generally modified by smaller amounts of cobalt or nickel. Beryllium-copper is widely considered to be indispensable for many end products in which hardness, high tensile strength, and resistance to fatigue with good electrical and heat conductivity are important.⁶ For the most part such products are small in size but find wide application as springs, diaphragms, and Bourdon tubes in measuring instruments, electrical contacts,⁷ and valve springs and guides. Most aviation instruments and many fire-control instruments contain beryllium-copper, and modern transport and bomber planes may have as many as 100 such parts. Other alloys, such as beryllium-nickel and beryllium-aluminum, have not found much application. An alloy containing about 15 to 50 percent beryllium, 5 to 20 percent silver, and the balance substantially aluminum is claimed to have a considerably greater tensile strength at high temperatures (400° to 600° F.) than that of alloys heretofore used in internal-combustion engines such as in newer aircraft engines.⁸ An extraordinary increase in corrosion resistance is claimed for the addition of 0.005 to 0.5 percent beryllium to magnesium.⁹ Beryllium oxide is important as a base for phosphors used

in fluorescent lamps.¹⁰ One pound of the oxide is sufficient for about 4,000 tubes. It is also of use for filaments and filament coatings in electric lamps, as electrodes in electron tubes, as a cathode heating element in radio tubes, and in other heating elements. Special crucibles and refractories are also made of the oxide. They are especially useful for high temperature work and are superior in strength to Al_2O_3 , ZrO_2 , ThO_2 , or synthetic MgOAl_2O_3 above $1,400^\circ\text{C}$.¹¹ and have been satisfactorily used for melting pure platinum and beryllium.

Technologic developments.—The Bureau of Mines conducted numerous tests on the concentration of beryl ores and on methods of beryllium analysis during 1944. The history and processing of beryllium were treated by Donald M. Liddell.¹² An improved method of analysis for beryllium in minerals and rocks was described.¹³

World production of beryllium ore, 1937-44, by countries, in metric tons¹

¹ In addition to countries listed, beryllium ore may also be produced in France, Italy, Kenya, Norway, Portuguese East Africa, Rumania, and U. S. S. R. Canada has produced beryl but has sold none.

² Data not available.

³ Estimate based upon United States imports.

⁴ Estimate.

⁵ January to June, inclusive.

Foreign review.—Australian output in 1943 was valued at £A16,009. Exports were greater in 1944 than in the preceding year. The discontinuance of purchases by United States agencies caused a large drop in Brazilian output. Prices for beryl and tantalite were fixed by the Coordinator of Economic Mobilization in May 1944.¹⁴ They correspond approximately with Metals Reserve Co. specifications dated May 1, 1943, which were superseded by the circular, Information Concerning the Purchase of Domestic Beryl and Tantalite-Columbite Ores, dated July 26, 1943. Beryl was first mined in Kenya, British East Africa, late in 1943. Small shipments were made by air in 1944. Small deposits in Uganda were also worked. Discovery of beryl in the Duncan River section of the Lardeau mining division in British Columbia was reported by the British Columbia Department of Mines. India has extensive pegmatite zones and it is believed to have commercially important beryl reserves; output has grown greatly during the war years. The Metal

¹⁴ *Mineração e Metalurgia, Fixados os preços da tantalita e do berilo*: Vol. 8, No. 44, July-September 1944, pp. 146-148.

Bulletin states ¹⁵ that most of the output came from scattered small pegmatite veins in Rajputana, and ore cobbled to over 10 percent BeO may have cost over Rs. 100 a ton at the deposits. Reserves in this area are probably not large. As a part of postwar industrial development plans it has been suggested that reduction of the ore should be carried out in India. Production in Madagascar was probably about 60 metric tons, of which 10 were shipped to the United States in January 1945, and 30 tons were left at Tamatave. Mining was discontinued about midyear. Beryl output of the Jooste Lithium Myne E/S, South-West Africa, was 38 tons in 1942, 36 tons in 1943, and 11 tons in the first half of 1944. In the same period exports from South-West Africa were 153 tons, all to the United Kingdom.

BORON

Production.—Shipments of ferroboron were 112 tons, with a boron content of about 10 tons in 1944 compared with 182 tons containing 26.5 tons of boron in 1943. A substantial part of the drop in shipment to consumers resulted from the 20-percent decline in alloy-steel production from 1943 to 1944. Shippers of ferroboron are the Electro Metallurgical Co., Molybdenum Corp. of America, and Ohio Ferro-Alloys Corp. Complex special boron-alloy addition agents that usually also contain several of the following elements—Al, Si, Ti, Zr, Ca, Mn, and V—are made by the above manufacturers of ferroboron and also by Titanium Alloy Manufacturing Co. and Vanadium Corp. of America. F. W. Berk & Co., Inc., produced for sale elemental amorphous boron of 82-to 86-percent B purity. This is believed to be the first domestic commercial output.

Uses.—The use of a minute quantity of boron added to steel by means of ferro-alloys known as special addition or “needling” agents, or as intensifiers, has been called a major contribution to the war effort. About 0.002 percent B appears to be the optimum amount; above 0.003 percent difficulties arise in hot working, and at 0.007 steel is made almost unworkable.¹⁷ The major effects are an increase in hardenability and improved mechanical properties in the quenched and drawn state; with suitable adjustment of steel chemistry substantial quantities of nickel, chrome, and molybdenum may be replaced. The use of boron with a free-machining steel showed a 31-percent increase in hardenability but a slight loss in machinability.¹⁷ Although improved hardenability resulting from boron additions is well-recognized, it has been stated that boron is “most useful in conjunction with important amounts of other alloying elements, and it plays but a small role in steels which are not thoroughly quenched or otherwise thoroughly hardened.”¹⁸ It has also been suggested that control of hardenability through boron additions in postwar steel will be ineffective because of nickel, chromium, and molybdenum residuals in scrap, except that alloy-free scrap and pig iron be used.¹⁹

Exports.—Almost the entire quantity of titanium concentrates and alloys exported in 1944 went to Canada. Mexico received 90 percent of the pigment exports; Cuba, 3 percent; Brazil, 2 percent; and other countries, 5 percent. Exports of tetrachloride dropped from 694 short tons in 1943 to 372 tons in 1944; 57 percent went to United Kingdom, 30 percent to Australia, and 13 percent to Canada. The total exports of titanium products (including concentrates) in 1944 were valued at 2¼ million dollars.

Exports of titanium products from the United States, 1940-40, by classes

³ Data cover last 4 months only.

STOCKS

Although inventories of ilmenite at the end of 1944 were about one-fourth larger than a year earlier in terms of TiO₂ content, they represented only about 5 months' supply at the 1944 consumption rate. Stocks of rutile increased about 12 percent by the year end and were probably more than 6 months' needs in view of the declining welding-rod output.

Stocks of titanium concentrates in the United States at end of year, 1943-44, in short tons

¹ Includes ilmenite and rutile content of mixed zirconium-titanium concentrates.

² Revised figures.

CONSUMPTION AND USES

The 19-percent increase in use of ilmenite in 1944 over that of the preceding year may be ascribed to the unsatisfied demand for titanium pigments. Consumption for pigments was 97 percent of the total, most of the remainder going into alloys and cemented carbides. The

diminished consumption of rutile was largely a reflection of the cut-back in welding-rod output; 73 percent of the total was used for welding-rod coatings, and nearly all the remainder for alloys.

Consumption of ilmenite and rutile in the United States, 1943-44, by products, in short tons

Product	Ilmenite		Rutile

¹ "Pigments" include all manufactured titanium dioxide, consumption of which in welding-rod coatings was 5,700 tons in 1943 and 3,900 tons in 1944.

² Consists of ilmenite used as a steel flux and rutile used in lamp-electrode coatings and as a steel deoxidizer.

Titanium pigments.—Both production and sales of titanium pigments continued on an upward trend and established new record highs. There was no pronounced change in the sales distribution pattern, which in 1944, according to a large manufacturer, was 75 percent for paint, varnish, and lacquer, 10 percent for paper, 2½ percent for welding-rod coating, 2 percent for floor coverings, 1½ percent for textiles, 1 percent for rubber, and 8 percent for other uses. Demand for pigments continued very strong, and distribution control was maintained under War Production Board Limitation Order M-353 by means of preference ratings. The order was slightly modified by an amendment November 4, 1944; it was revoked March 26, 1945, but was simultaneously replaced by Conservation Order M-340, Miscellaneous Chemicals. The use of titanium pigments has continued to grow at the expense of both lithopone and white lead because of its exceptionally high hiding power. The marketing of the rutile type in 1941 and the chalk-resistant rutile variety in 1942 provided new pigments with 20 to 40 percent higher hiding power than the anatase form that was the only titanium dioxide pigment commercially available before 1941. Hiding power, color, tintability, and chalk resistance have led to the widespread use of these pigments as camouflage or protective coating on ships, planes, and tanks by the United States Government during the war.⁷

Welding-rod coatings.—Production of titanium-coated welding rods in 1944 was 382,000 short tons compared with 481,000 tons produced in 1943 and 321,000 tons in 1942. The indicated 20-percent decline

⁷ Chemical and Metallurgical Engineering, Report on Paints and Varnishes; Vol. 51, No. 11, November 1944, p. 122.

in use of titanium dioxide mirrored changes in armament- and ship-construction programs and impending further cut-backs.

Titanium alloys.—The titanium ferro-alloys are important additives in the production of rimming and killed steels. The titanium-treated steels are cleaner, give higher ingot yield, and have generally better physical characteristics than untreated steels and some of those treated with other deoxidizers. In these applications there is little or no titanium residual in the finished steel. Titanium is also used as an alloying element, especially in stainless steels where its main effect is through carbide control to inhibit intergranular corrosion and embrittlement. A titanium alloy steel, now in commercial production, has made possible the direct application of white or light pastel vitreous enamels to steel without the use of a ground-coat enamel. This one-coat enameling steel possesses exceptional cold-drawing characteristics and resistance to sagging or bending at enamel firing temperatures and is reported not to age-strain.^{8 9}

Other uses.—Titanium tetrachloride was used as a screening smoke during the First World War and has been employed in substantial volume during the present conflict. At first it was usually prepared by chlorinating rutile in the presence of carbonaceous material. Subsequently and during the current war, titanium cyanonitride—an electric-furnace product—was reacted with chlorine to make the tetrachloride. These were high-temperature processes requiring careful controls, and the product was likely to be contaminated with impurities contained in the raw materials. Later, better results were obtained by substituting pigment titanium dioxide briquetted with finely ground charcoal and a binder in place of the cyanonitride.

PRICES

No price changes affected any form of titanium in 1944. Ilmenite and rutile prices were fixed by the Office of Price Administration February 22, 1943 (Regulation 327), at levels prevailing in March 1942. Ilmenite, 60 percent TiO_2 , was nominally quoted at \$28–\$30 a long ton, f. o. b. Atlantic seaboard, and rutile, 94 percent TiO_2 , at 8–10 cents a pound. Steel quoted ferrotitanium, ton lots, at \$1.23 per pound of contained Ti for 40- to 45-percent grade and \$1.35 for 20- to 25-percent grade; and ferrocarbontitanium, 15–20 percent Ti, at \$142.50 a short ton for 6- to 8-percent carbon and \$157.50 for 3- to 5-percent carbon. Titanium metal, 96–98 percent, was listed at \$5–\$5.50 a pound. The base price of manufactured titanium dioxide remained fixed at $14\frac{1}{2}$ – $16\frac{1}{2}$ cents a pound.

TECHNOLOGY

The Bureau of Mines and Geological Survey made field studies on Wyoming titaniferous magnetite. The Bureau conducted laboratory research on metal and alloy production and on ore dressing of various raw materials.

The Humphreys spiral concentrator has efficiently separated heavy minerals from natural sands, with high recoveries. It is reported to be relatively insensitive to changes in pulp density and quantity and

⁸ Comstock, G. F., and Wainer, E., New Titanium Steel for Vitreous Enameling: *Iron Age*, vol. 155, No. 7, February 1945, pp. 60–63, 152–153.

⁹ Comstock, G. F., Strain Aging of Killed Low-Carbon Steel, with Particular Reference to the Effect of Titanium: *Proc. Am. Soc. Testing Materials*, vol. 43, 1943, pp. 521–541.

grade of feed, and to particle size or shape. In the first commercial application—Oregon chromite-bearing beach sands—a concentration ratio of 2.25 : 1 was obtained, with a recovery of 98 percent.¹⁰ The Florida beach-sand spiral feed has 5½ to 11 percent heavy minerals. The concentrate ranges from 88 to 96 percent heavy minerals, mostly ilmenite and rutile, but was held close to 92 percent. Recovery exceeds 95 percent.¹¹

WORLD PRODUCTION

Data on world production of ilmenite and rutile in recent years are shown in the following table.

World production of titanium concentrates (ilmenite and rutile), 1937-44, by countries, in metric tons

⁴ Includes 26 tons of garnet-ilmenite.

⁵ Bureau of Mines not at liberty to publish figures.

⁶ In addition, zircon-rutile-ilmenite concentrates were produced as follows—1937: 73 tons; 1938: 98 tons.

⁷ Less than 1 ton.

⁸ Exports.

Australia.—Beach-sand deposits similar to those of New South Wales, which have been worked for a number of years, are being prospected and developed along 60 miles of potentially productive Queensland coast. Approximate mineral composition of the deposits, usually called "black sands," is as follows: Zircon, 40 to 45 percent; rutile, 30 to 35 percent; and ilmenite, 20 percent. The Minerals Deposits Syndicate in Queensland is now producing a high-grade monazite concentrate. The product from most of the plants is a mixed concentrate, but efforts are being made to produce clean concentrates of individual minerals, mainly rutile and zircon.¹²

¹⁴ Engineering and Mining Journal, Queensland: Vol. 145, No. 10, October 1944, pp. 164, 165.

Brazil.—Brazil has the raw materials for the production of titanium oxide, and it is reported that the establishment of such an industry is being considered.¹³ There are large quantities of rutile in Ceara, Goiaz, and Minas Gerais. Brazil's deposits of ilmenite and monazite are found on the coast of Espirito Santo and Bafa and are among Brazil's long-exploited minerals.

Ceylon.—Ilmenite is found in large quantities on the beaches of Ceylon. The Ceylon Government proposes to establish a plant for manufacturing paints in the island, using ilmenite as the principal pigment base.¹⁴

Egypt.—Ilmenite, zircon, and monazite are obtained in Egypt from black sand at the mouth of the Nile near Rosetta and Damietta. The minerals are extracted in plants at Rosetta and Alexandria.¹⁵

India.—Although the Travancore ilmenite deposits may be approaching exhaustion, other ilmenite-bearing sands are available along the east coast.¹⁶ Fairly large deposits of titaniferous iron ores occur in Mysore.¹⁷ Extensive deposits are also found in Singhbhum and Mayurbhanj which may develop into a future source of titanium.¹⁸

United Kingdom.—Official prices for rutile are unchanged at £54 a long ton for Cameroun concentrates, £42–£50 for Indian concentrates, and £45 for Australian concentrates. Indian ilmenite, 52–54 percent TiO_2 , is quoted at about 30s. per ton, f. a. s.¹⁹ Ferrotitanium price remained at £100 per long ton for the 2- to 3-percent carbon grade (20–25 percent Ti) and 1s. 3½d. per pound for the carbon-free grade.²⁰ Titanium pigment manufacturers in the United Kingdom have formed a Titanium Pigment Manufacturers' Specification Committee whose reported sole object is to assist in the preparation of official specifications involving titanium oxide.²¹

BARIUM AND STRONTIUM

The United States is believed to be the largest producer of barium and strontium and their aluminum or aluminum-magnesium alloys; output has been several thousand pounds annually. These metals and others, principally aluminum, calcium, magnesium, thorium, uranium, zirconium, and mischmetal (cerium and lanthanum mostly), are or have been used as "getters"¹ for the removal of residual gases and those evolved during service in all radio tubes and in virtually all other radionic tubes. Barium has been found to be the best all-round material, but it is ordinarily used in alloyed form. Barium-magnesium getter alloys contain 25-30 percent magnesium, barium-aluminum 50 percent barium, barium-aluminum-magnesium 1 part of the first to 3 parts of the second, and that containing strontium about 14 percent barium, 25 percent strontium, and the remainder magnesium. The getter materials are formed in tablets or pellets ranging in weight from about 2 to 40 milligrams, with the most commonly used sizes between 4 and 12 milligrams. The growth of the radio and radionic tube industry affords a measure of barium consumption. The dollar value of tube output in 1941 was 53 million; in 1942, 132 million; in 1943, 304 million; and in 1944, 406 million.

BERYLLIUM

The recession in demand for beryllium that became marked in the second half of 1943 continued in 1944 and resulted in a drop in consumption of one-fourth compared with 1943. Imports declined more than one-third as a result of contract cancellations but were still so much above current consumption that year-end stocks were equivalent to about 2½ years' requirements at the 1944 use rate. Allocation of beryllium under War Production Board Conservation Order M-160, was lifted August 19.

Domestic mine production.—Shipments from mines established a new record 9 percent above the preceding peak in 1943; however,

¹ A comprehensive review of production and application of getters is given in *Light Metals* (London) *Gettering and Getters*: Vol. 7, Nos. 72-73, January-February 1944, pp. 34-52, 77-94.

they covered less than one-fifth of domestic needs. Production expansion was largely a response to Metals Reserve Company increased buying price. The Bureau of Mines and Geological Survey examined beryl deposits in New England, the southern Appalachians, Black Hills, and Rocky Mountains. An unusual beryllium-bearing rock was described by Jahns,² and an occurrence of beryl associated with tantalum and lithium minerals was described by Jahns and Wright.³

Beryl crystals of great size are occasionally uncovered. The writer is indebted to Arthur F. Johnson, consulting mining engineer of Keystone, S. Dak., for the following information concerning those found on the property of the Black Hills Keystone Corp. In what is called the No. 2 Dike, one crystal mass that contained 24 tons of beryl was mined in 1933. Subsequently three others that provided 16, 11, and 6 tons of beryl, respectively, were excavated. In July 1942 a crystal 19 feet long was uncovered. At the small end it was 18 inches in cross section and at the other was slightly over 5 feet. This crystal weighed 34 tons. Not until November 1943 were any large crystals or masses found in the No. 1 Dike. Then, one mass without definite crystal form produced 26.5 tons. Late in 1944 a gigantic crystal was mined. The cross section was not determined; but the length was 28 feet, and it provided 61½ tons of beryl. The Highland Lode mine near Custer, S. Dak., is also well-known as a source of large crystals. In 1940 one yielded 7 tons, and in April 1944 one of 5½-ton size was removed.⁴ Crystals weighing up to 1½ tons have been reported from Beryl Mountain near Keene, N. H.⁵

Foreign trade.—Withdrawal of United States Government support in foreign markets, especially in Argentina and Brazil, brought about a 37-percent drop in imports from the 1943 record level. British countries, however, furnished larger tonnages than in 1943. Exports were 19,065 pounds of ore, 84,229 pounds (\$68,090) of metal, alloys, and scrap, and 2,042 pounds (\$7,067) of salts and compounds.

¹ Less than 1 ton.

² 5 tons additional from Mozambique were reported to the Bureau of Mines.

Stocks.—Stocks in the hands of consumers and dealers were reduced to 131 tons from 1,036 at the beginning of the year. Miners disposed of their inventories in anticipation of a price drop after the termination of the Metals Reserve Company purchase program on December 31, 1944. That agency's small-lot purchase depots transferred their beryl stocks early in 1945 to stock piles in consuming areas near Reading, Pa., and Cleveland, Ohio.

Prices.—The Metals Reserve Company raised its buying price for domestic beryl from \$12 a short-ton unit of beryllium oxide to \$14.50, f. o. b. mine in May 1944 and maintained it at that level for the remainder of the year. Beryllium-copper master-alloy was quoted at \$15 a pound contained beryllium.

Uses.—The major use of beryllium is as an alloying element with copper, usually containing about 2 percent Be and generally modified by smaller amounts of cobalt or nickel. Beryllium-copper is widely considered to be indispensable for many end products in which hardness, high tensile strength, and resistance to fatigue with good electrical and heat conductivity are important.⁶ For the most part such products are small in size but find wide application as springs, diaphragms, and Bourdon tubes in measuring instruments, electrical contacts,⁷ and valve springs and guides. Most aviation instruments and many fire-control instruments contain beryllium-copper, and modern transport and bomber planes may have as many as 100 such parts. Other alloys, such as beryllium-nickel and beryllium-aluminum, have not found much application. An alloy containing about 15 to 50 percent beryllium, 5 to 20 percent silver, and the balance substantially aluminum is claimed to have a considerably greater tensile strength at high temperatures (400° to 600° F.) than that of alloys heretofore used in internal-combustion engines such as in newer aircraft engines.⁸ An extraordinary increase in corrosion resistance is claimed for the addition of 0.005 to 0.5 percent beryllium to magnesium.⁹ Beryllium oxide is important as a base for phosphors used

in fluorescent lamps.¹⁰ One pound of the oxide is sufficient for about 4,000 tubes. It is also of use for filaments and filament coatings in electric lamps, as electrodes in electron tubes, as a cathode heating element in radio tubes, and in other heating elements. Special crucibles and refractories are also made of the oxide. They are especially useful for high temperature work and are superior in strength to Al_2O_3 , ZrO_2 , ThO_2 , or synthetic MgOAl_2O_3 above $1,400^\circ\text{C}$.¹¹ and have been satisfactorily used for melting pure platinum and beryllium.

Technologic developments.—The Bureau of Mines conducted numerous tests on the concentration of beryl ores and on methods of beryllium analysis during 1944. The history and processing of beryllium were treated by Donald M. Liddell.¹² An improved method of analysis for beryllium in minerals and rocks was described.¹³

¹ In addition to countries listed, beryllium ore may also be produced in France, Italy, Kenya, Norway, Portuguese East Africa, Rumania, and U. S. S. R. Canada has produced beryl but has sold none.

² Data not available.

³ Estimate based upon United States imports.

⁴ Estimate.

⁵ January to June, inclusive.

Foreign review.—Australian output in 1943 was valued at £A16,009. Exports were greater in 1944 than in the preceding year. The discontinuance of purchases by United States agencies caused a large drop in Brazilian output. Prices for beryl and tantalite were fixed by the Coordinator of Economic Mobilization in May 1944.¹⁴ They correspond approximately with Metals Reserve Co. specifications dated May 1, 1943, which were superseded by the circular, Information Concerning the Purchase of Domestic Beryl and Tantalite-Columbite Ores, dated July 26, 1943. Beryl was first mined in Kenya, British East Africa, late in 1943. Small shipments were made by air in 1944. Small deposits in Uganda were also worked. Discovery of beryl in the Duncan River section of the Lardeau mining division in British Columbia was reported by the British Columbia Department of Mines. India has extensive pegmatite zones and it is believed to have commercially important beryl reserves; output has grown greatly during the war years. The Metal

¹⁴ *Mineração e Metalurgia, Fixados os preços da tantalita e do berilo*: Vol. 8, No. 44, July-September 1944, pp. 146-148.

Bulletin states¹⁵ that most of the output came from scattered small pegmatite veins in Rajputana, and ore cobbled to over 10 percent BeO may have cost over Rs. 100 a ton at the deposits. Reserves in this area are probably not large. As a part of postwar industrial development plans it has been suggested that reduction of the ore should be carried out in India. Production in Madagascar was probably about 60 metric tons, of which 10 were shipped to the United States in January 1945, and 30 tons were left at Tamatave. Mining was discontinued about midyear. Beryl output of the Jooste Lithium Myne E/S, South-West Africa, was 38 tons in 1942, 36 tons in 1943, and 11 tons in the first half of 1944. In the same period exports from South-West Africa were 153 tons, all to the United Kingdom.

BORON

Production.—Shipments of ferrobaboron were 112 tons, with a boron content of about 10 tons in 1944 compared with 182 tons containing 26.5 tons of boron in 1943. A substantial part of the drop in shipment to consumers resulted from the 20-percent decline in alloy-steel production from 1943 to 1944. Shippers of ferrobaboron are the Electro Metallurgical Co., Molybdenum Corp. of America, and Ohio Ferro-Alloys Corp. Complex special boron-alloy addition agents that usually also contain several of the following elements—Al, Si, Ti, Zr, Ca, Mn, and V—are made by the above manufacturers of ferrobaboron and also by Titanium Alloy Manufacturing Co. and Vanadium Corp. of America. F. W. Berk & Co., Inc., produced for sale elemental amorphous boron of 82-to 86-percent B purity. This is believed to be the first domestic commercial output.

Uses.—The use of a minute quantity of boron added to steel by means of ferro-alloys known as special addition or “needling” agents, or as intensifiers, has been called a major contribution to the war effort. About 0.002 percent B appears to be the optimum amount; above 0.003 percent difficulties arise in hot working, and at 0.007 steel is made almost unworkable.¹⁷ The major effects are an increase in hardenability and improved mechanical properties in the quenched and drawn state; with suitable adjustment of steel chemistry substantial quantities of nickel, chrome, and molybdenum may be replaced. The use of boron with a free-machining steel showed a 31-percent increase in hardenability but a slight loss in machinability.¹⁷ Although improved hardenability resulting from boron additions is well-recognized, it has been stated that boron is “most useful in conjunction with important amounts of other alloying elements, and it plays but a small role in steels which are not thoroughly quenched or otherwise thoroughly through hardened.”¹⁸ It has also been suggested that control of hardenability through boron additions in postwar steel will be ineffective because of nickel, chromium, and molybdenum residuals in scrap, except that alloy-free scrap and pig iron be used.¹⁹

¹⁹ McQuaid, Harry W., Postwar Steel and Its Treatment: Metal Progress, vol. 46, No. 5, November 1944, p. 1072.

Prices.—Ferroboron, 17.5 percent B, carlots, was quoted at \$1.20 a pound. Elemental amorphous boron was offered at \$15 a pound, f. o. b. works, in 100-pound lots or over. Higher prices were asked for smaller lots.

CALCIUM

The Electro Metallurgical Co., Metal Hydrides Co., and New England Lime Co. produced calcium metal, hydrides, and alloys in 1944. Production figures are not available, but it has been estimated that output substantially exceeded 100,000 pounds. The alkaline earth metals calcium, barium, and strontium rank fourth, tenth, and fourteenth, respectively, among the 52 metallic components of igneous rocks²⁰ and are therefore relatively abundant. However, the high cost of preparation and circumscribed markets make for a wide disparity between the price of the raw material and metal product. Calcium metal, 97–98 percent, was quoted at \$1.25 a pound in ton lots for the first 10 months of 1944 and then rose to \$1.85, where it remained until the year end.

The metal is used mainly as a deoxidizer for stainless and other steel that must be exceptionally free of harmful impurities. The metal and its hydrides are effective in preparing difficultly reducible metals. Alloys, especially with lead, are growing in use. Methods of analyses have been given,²¹ and the growth of the Electro Metallurgical Co. plant was described.²²

¹ No transactions reported during 1943 and 1944.

CERIUM AND THE RARE-EARTH METALS

Cerium master alloy (misch metal) and commercially pure cerium metal were produced by the Cerium Metals Corp., at Niagara Falls, N. Y., and by the Cooper Metallurgical Laboratory, Cleveland, Ohio. The Cerium Metals Corp. gives the following composition for its cerium standard alloy: Cerium, 45–50 percent; lanthanum, 22–25; neodymium, 15–17; praeosodymium, terbium, yttrium, illinium, and samarium combined, 8–10; iron, 0–5; silicon, 0.1–0.3; and traces of calcium, carbon, and aluminum. Many common and precious metal-cerium master alloys are also available.

An excellent survey of the present position of the chemistry of the rare earths was published.²³ Methods of separation, identification, and

determination were given. Because cerium is the most widespread and the most easily extracted of the rare-earth metals most of available data on applications relate to it.²⁴ The pyrophoric ferro-alloy of cerium is the most widely used material for lighter flints; other important uses are in tracer bullets and other pyrotechnics and as a getter in radionic tubes. Minor quantities are used in aluminum²⁵ and magnesium alloys. The use of 4.5 and 5 percent cerium in aluminum and magnesium alloys in parts of German aviation motors was described.²⁶ In the ceramic field cerium is used as a component of glass and as an abrasive.²⁷ Lanthanum oxide is used for the preparation of color-free optical glasses.²⁸

Canada was the sole source of imports in 1944; these were 20,240 pounds of alloys (\$91,203) and 106 pounds of compounds (\$322), compared with 5,720 pounds of alloys (\$27,589) and 119 pounds of compounds (\$304) in 1943. Exports were 2,651 pounds (\$8,978) of ore and concentrates, none in 1943; and 38,918 pounds (\$116,975) of metal and alloys compared with 54,797 pounds (\$148,891) in the preceding year.

COLUMBIUM AND TANTALUM

Record imports of columbite and tantalite with contraction in demand, especially for tantalite, permitted relaxation of use controls by the War Production Board. In October 1944 the Board classed columbium as in adequate supply to meet war and essential industrial needs. On April 19 an amendment, Preference Order M-156, raised the quantity of tantalum that could be delivered or received monthly from 1 ounce to 3 kilograms. In October it was classed as available for all essential uses and on December 6, 1944, all restrictions on use were lifted by revocation of Order M-156.

Domestic production.—Columbium and tantalum ore shipments declined 44 and 23 percent, respectively, compared with 1943. Distribution of shipments by States for 1944 is not available for publication; however, the major producer was again Arthur Montgomery of Dixon, N. Mex., who shipped 4,720 pounds of microlite of 69 to 70-percent Ta₂O₅ content.

¹ Classified by U. S. Department of Commerce as British East Africa.

² Classified by U. S. Department of Commerce as from New Zealand, which has no recorded production.

Prices.—The Metals Reserve Company price schedule,²⁹ which included columbite and tantalite, remained effective throughout the year. E&MJ Metal and Mineral Markets quoted tantalum ore at \$2-\$3 a pound of contained Ta₂O₅; tantalum metal (sheet) at \$143 and rod \$160.60 per kilogram; ferrocolumbium, 50-55 percent Cb, at \$2.25-\$2.30 a pound of contained Cb; and columbium metal (sheet) \$500 a kilogram and rod at \$560. All were unchanged throughout the year.

Uses.—The principal use of columbium continued to be as an addition agent to stainless steels, where it acts as a stabilizer by suppressing the formation of harmful chromium carbides and thereby imparts enhanced corrosion resistance. This is of great value in airplane-engine parts and auxiliaries; the rapid expansion in rocket firing presents an extended field for high-temperature corrosion-resistant materials. From 1.75 to 2.75 percent columbium was found in tungsten cores of German projectiles.³⁰ Columbium metal has yet found little application, but markets may be developed. A new process for the production of the metal was announced by the Fansteel Metallurgical Corp.³¹ The major uses for tantalum in relative order of importance remained: As metal in radar and other electronic tubes; as fluoride as a catalyst in synthetic rubber manufacture; and as oxides and carbides in high-speed cutting tools. The first two named account for about 65 percent of consumption.

Foreign review.—The Jantar Nigeria Co., Ltd., produced 327 long tons of columbite in the year ended September 30, 1944, compared

²⁹ See Minor Metals chapter, Minerals Yearbook, 1943.

³¹ Iron Age, Reducing Columbium Oxide: Vol. 153, No. 15, April 13, 1944, p. 70.

with about 500 tons in the preceding business year. Contracts with American purchasers were renewed for 1945.³² Tantalo-columbite has been mined in the Belgian Congo since 1934. Most of the output has come from the Geomines properties, where it is a byproduct of cassiterite mining. Reserves were estimated to contain 2,500 metric tons of commercial-grade concentrate at the beginning of 1943. The concentrates contain about 28-30 percent Ta_2O_5 and 30-35 percent Cb_2O_5 . Exports were 242,198 pounds in 1943 and estimated to be 310,000 in 1944. Brazil maintained its position as the world's premier producer. As many as 400 "mines" were in operation. Exports were 253.6 metric tons in 1944, all destined for the United States. Unusually rich deposits of columbium were reported³³ to have been uncovered in the Vishnevi Mountains near Kasli, Chelyabinsk Oblast, U. S. S. R. In January 500 kilograms of concentrates were made. A detailed review of world tantalite resources as of 1944 was published.³⁴

GERMANIUM

The Eagle-Picher Lead Co., Joplin, Mo., in 1944 produced a small quantity of germanium metal and salts. The Metal Bulletin, London, continued to quote germanium metal (99.5 percent) at 19s. 6d. a gram. Among the many rare elements found in coal, germanium and gallium appear to be the only ones that it may be feasible to recover commercially.³⁵ In England flue dusts from chemical works have been found to contain large enough quantities of those elements that they may have commercial possibilities.

INDIUM

Domestic production.—The Bureau of Mines may not publish output figures; however, production appears to have outrun demand substantially, with a resultant sharp rise in inventories.³⁶ In 1944 the producers of indium metal and salts were American Metal Co., Ltd., American Smelting & Refining Co., Anaconda Copper Mining Co., and National Zinc Co. Anaconda continued to dominate the field.

Prices.—Stock accumulations acted as a powerful price depressant, according to the source above named. In March 1944 the metal (99.9 percent indium) price had been reduced from \$10 a troy ounce to \$7.50-\$8.50. By March 1945 sales competition was so great that price became a matter of negotiation. It was said that purchases could be made at \$4, whereas it sold at \$30 in 1936.

Use.—The principal application developed to date has been as an alloy additive in bearing metals to which the indium contributes strong resistance to corrosion by lubricating oil acids, and enhanced fatigue resistance³⁷ with low coefficient of friction.³⁸

RADIUM AND URANIUM

Demand for radioactive materials, especially uranium and radium, continued to be strong in 1944. An approximate index is given by the weight of radioactive specimens tested annually by the National Bureau of Standards. In 1944 such specimens contained 79,746 milligrams of radium and 856 milligrams of mesothorium compared with 35,193 and 2,276 milligrams, respectively, in 1943. Amendments to War Production Board Conservation Order M-285, greatly tightened control over uranium ores and products. Imports of radium salts and radioactive materials were the highest on record.

Domestic production.—Virtually the sole domestic source of radium and uranium has been the carnotite ore (also the source of much domestic vanadium) of the Colorado plateau region embracing parts of Arizona, Colorado, and Utah. Small quantities of pitchblende have also been mined. Some was found in sinking on the Wood lode near Central City, Gilpin County, Colo., in 1872, but it was not at once recognized and was thrown away. Later the remainder—amounting to about 3 tons, said to have contained about 70 percent U_3O_8 —was mined and sold in England at \$1.50 a pound. Small quantities were also mined from the nearby Black Hawk and Kirk mines. Up to about 1899 the total production of uraninite (pitchblende) probably had reached 100 tons. Thereafter it dropped greatly because of the discovery of carnotite (essentially a hydrated vanadate of uranium and potassium) in Colorado. Up to about 1906 the output (a few hundred tons annually) was shipped mostly to France and Germany for use as a ceramic colorant and as a uranium alloy-additive to steel. Subsequently it was used as a source of radium, but exports ceased at the beginning of the First World War. Radium was first produced commercially in United States in 1913; soon this country became the major world producer and maintained that position until 1922, when the exceptionally high-grade Belgian Congo ores—up to 60 percent uranium oxide—made Belgium the dominant world factor. In the period 1906–22 mine production of carnotite ore had reached a peak of over 13,000 tons annually; but the average was less than 3,700 tons, and much of this material was used for vanadium recovery with the uranium and radium being lost in tailings. The total United States radium production up to 1925 was estimated ³⁹ by Hess to be about 250 grams. From 1922 to 1936 carnotite production was small, and again nearly all was consumed for its vanadium content and to a small extent for uranium salts; less than 1 gram of radium was produced. After 1936 mine production of carnotite ore increased many fold and continued to rise through 1943 but declined substantially in 1944 with the drop in vanadium requirements. In this period the ores continued to be treated primarily for their vanadium content, but beginning in 1940 recovery of uranium became important. The United States Vanadium Corp. erected at Uravan, Colo., a re-treatment plant of 50 tons daily capacity for uranium recovery, and at least one other tailings re-treatment plant was put into operation in 1943. Data on domestic recovery of uranium and radium have not been available for 3 years. It is evident, however, that substantial output has been obtained from tailings re-treatment, but the potential output is materially greater.

³⁹ Hess, Frank H., *Rare Metals, Radium, and Uranium*: Bureau of Mines Mineral Resources of the United States 1926, part I, p. 268.

Foreign trade.—A new high record was set for radium imports in 1944. All the radium, mesothorium, and 4,675 pounds of uranium oxide and salts imported came from Canada. The remainder—5,750 pounds of uranium oxide and salts—was received from the United Kingdom.

In Canada the Eldorado Mining & Refining, Ltd., mine on Great Bear Lake, N. W. T., and the refinery at Port Hope, Ontario, worked full time as a Crown operation on essential and war needs.⁴⁰ Radium and uranium salts are the major products. The plant capacity has been estimated at 80 to 100 grams of radium annually. The International Uranium Mining Co., Ltd., whose property is about 10 miles from the Eldorado mine, was reported to have undertaken an exploratory drilling campaign in 1943.

According to Chemical Age,⁴¹ China received 50 milligrams of radium for therapeutic use.

In keeping with its continental despoliation plans, Germany was said to have removed 8 grams of radium from the Curie Foundation, leaving only 6 grams in Paris. Italy was also forced to turn over its stocks of radium.⁴² It has been planned to recover uranium and ferro-alloy elements from residues of the Swedish State-owned shale-oil plant at Kvarntorp.⁴³

In Peru the State reserved to itself the rights to all radioactive mineral deposits in seven of the mining districts of the Department of Arequipa. A uranium deposit was reported to have been discovered in the Alaisk Ridge in Kirghizia, U. S. S. R. Mining is planned on an industrial scale after completion of exploration.⁴⁴ Pitchblende and other radioactive minerals have been reported⁴⁵ found in the State of Merida, Venezuela.

Radium salts, radioactive substitutes, and uranium ore and compounds imported for consumption in the United States, 1940-44

Year	Radium salts			Radioactive substitutes ¹ (value)	Uranium ore		Uranium oxide and salts	
	Grams	Value			Pounds	Value	Pounds	Value
		Total	Average per gram					
1940.....	30.311	\$748,097	\$24,700	\$5,650	2,400,198	\$2,110,927	240,199	\$388,355

⁴⁵ Engineering and Mining Journal, vol. 145, No. 10, October 1944, p. 155.

Uses.—Until recent years the major use for radium has been in the treatment of cancer and skin diseases. In 1939 about 157 grams of radium were in medical use in the United States. It had been estimated that such requirements were increasing at the rate of about 10 grams yearly, but the use of high-voltage X-rays and radioactivated materials has been competitive in this field.

Radium has been successfully used in treating an inflammation of the middle ear that has been noticeable among aviators who fly at high altitudes or engage in dive bombing.⁴⁶ Radium and radioactive substances are also reported to have speeded the production of penicillin.⁴⁷ About 1933 radium was first used industrially for the non-destructive testing of relatively heavy metals for hidden defects. This nondissipative use has grown greatly, especially under the war-time stimulus for speedy production of high-grade matériel that contains heavy castings or forgings and a tremendous quantity of welded joints. Much industrial radiography is also carried out with X-ray apparatus, but the greater penetrating power of the gamma rays of radium compared with X-rays and simplicity of equipment and relative ease of transport give some advantage to radium, especially for examination of heavier sectioned material as in the case of steel, over 3 to 4 inches in thickness. In 1944 it was estimated by the War Production Board that about 36 grams were put into industrial and medical radiographic use, largely the former, compared with 25 grams in 1943.

During and after the First World War much use was made of radium-bearing self-luminous paints for watch, clock, and instrument dials. This application fell into disrepute because of the numerous deaths directly attributable to radium poisoning or exposure to the constantly discharged rays. However, effective protective procedures have been developed, and their application has made possible without hazard the use of radioactive luminous compounds. The compound most used, known as 14112, was developed by the Air Corps. Although it contains about $2\frac{1}{2}$ times as much radium as the 38 M used in the First World War, it loses 90 percent of the emitted light intensity in one-half second after removal of the ultraviolet excitation, thus removing the danger of showing a plane's position to an adversary.⁴⁸ Wartime applications for aircraft and ship instrument dials, ground direction markers, gun sights, compasses, and other instruments consumed about 50 grams in 1944 compared with 75 grams in 1943 and 40 grams in 1942.

Uses of uranium for the most part have been (as salts) in ceramics and as catalysts in the chemical industry. About the beginning of the century there was interest in its use for armor plate and again in the early 1920's for the manufacture of high-speed steels, but they did not attain general acceptance because other tool steels of essentially the same characteristics could be more readily and cheaply produced. However, some alloys have been prepared, and ferrouanium, containing about 39 percent U, has been offered for sale in recent years.

Uranium has found virtually no employment as metal. Scientific and public interest, however, was highly aroused by the potential

⁴⁶ Science News Letter, Radium Successful for Treating Aviator's Ear: Vol. 46, No. 19, November 4, 1944, p. 297.

⁴⁸ Steel, Luminous Paint: Vol. 116, No. 8, February 19, 1945, pp. 120, 122, 125.

development of atomic energy from nuclear fission in which the uranium isotope of atomic mass number 235 offers the greatest possibilities. The proportion of U^{235} to the "normal" uranium atom U^{238} in all uranium minerals and salts is 1 to 139. Separation and isolation of uranium 235 was accomplished in the United States at least as early as 1939 by means of the atom-smashing cyclotron as a source of bombarding neutrons. The energy expenditure, however, was about 15 times that released. Other more effective methods have been employed since. Thermal diffusion apparatus offers some promise of relatively speedy concentration of the U^{235} atom. A mixture of radium and beryllium embedded in paraffin will serve as a source of neutrons for the bombardment of the uranium atom 238 which will then split as a result of chain reaction.

If a method of production with concomitant controls of the enormous energy release can be effected, fantastic possibilities arise. As an explosive the total energy content, weight for weight, is said to be some 18 billion times greater than the energy yielded by any known chemical combustion process. In other words, an atomic explosion would be many million times more powerful than that of any known explosive.

Foreign production.—The radium plant of the Cie. Générale Metallurgique de Hoboken at Oolen, Belgium, was found to be intact after the reoccupation of Belgium by Allied armies and was said to be in operation in the spring of 1945. It had been in German hands from May 1940. This was believed to be the world's largest radium refinery and treated ores from the Belgian Congo. During the German occupation period those ores had been sent to Canada and the United States for treatment. The Belgian Congo Government presented 3 grams of radium in 1944 to the Soviet Union for use in military hospitals.⁴⁹

SELENIUM AND TELLURIUM

Domestic production.—Selenium output dropped 24 percent in 1944 from the 1943 record high, and producers' shipments fell 19 percent. Tellurium production rose 23 percent, but sales continued to decline and were the lowest since 1938. Year end producers' stocks of selenium were greater than a year's needs at the 1940-44 average, and those of tellurium were the equivalent of about $1\frac{1}{2}$ years' requirements at the period's average.

Salient statistics of elemental selenium and tellurium in the United States, 1940-44

Year	Selenium					Tellurium ¹		
	Production (pounds)	Producers' sales ² (pounds)	Producers' stocks at end of year (pounds)	Imports ³		Production (pounds)	Producers' sales ² (pounds)	Producers stocks at end of year (pounds)
				Pounds	Value			
1940.....	328, 731	368, 709	206, 800	134, 429	\$198, 163	85, 622	88, 996	85, 700
1941.....	620, 493	681, 650	146, 000	197, 873	268, 161	224, 639	239, 983	20, 400
1942.....	506, 426	316, 613	341, 900	83, 666	127, 004	224, 132	98, 796	145, 700

¹ Includes tellurium content of small quantity of oxide.

² Bureau of Mines not at liberty to publish value. Quantities for 1942-44 represent producers' shipments.

³ Includes selenium salts.

⁴⁹ Foreign Commerce Weekly, Belgian Congo Donates Radium to U. S. S. R.: Vol. 17, No. 11, December 9, 1944, p. 36.

Foreign trade.—Selenium imports came entirely from Canada in 1944. Tellurium is not shown separately in import records. Producers reported exports of 13,191 pounds of selenium including that in compounds and 288 pounds of tellurium in 1944. In 1943 the respective figures were 7,218 and 233 pounds.

Prices.—According to E&MJ Metal and Mineral Markets, prices of selenium (black, powdered 99.5 percent) and of tellurium were nominal and unchanged at \$1.75 a pound throughout the year.

Uses.—The glass industry absorbs a large part of the selenium production; some is used in rubber manufacture and lesser quantities are used in photoelectric cells, stainless steels, and copper. As an antioxidant selenium improves lubricating oils.⁵⁰ The recovery of selenium was described.⁵¹ The principal use for tellurium has been in rubber compounding. It is also used in lead to provide work hardenability and to improve resistance to acids. Minute quantities added to cast iron increase chill depth, hardness, and resistance to some acids.⁵² It has been suggested that it may be a suitable alloying element for high-temperature-resistant material needed for jet-propulsion planes or rockets.⁵³

Foreign production.—Preliminary figures for Canada's production of selenium and tellurium in 1944 were, respectively, 345,000 pounds and 56,900 pounds compared with 374,013 pounds and 8,600 pounds in 1943.

THALLIUM

The 1944 production of thallium in the United States increased slightly over that of 1943. The American Smelting & Refining Co., the sole producer, recovers the metal as a byproduct from cadmium production. Most of the metal is converted to the poisonous thallium sulfate that is used as a rodenticide and for the extermination of ants and some other insects. Based on estimates furnished by the Fish and Wildlife Service, domestic requirements for thallium sulfate would be about 6,000 pounds for the fiscal year beginning July 1, 1945, and about 7,500 pounds for the following year. In addition thereto there have been heavy demands by the military for rat control in the war theatres. The probable supply-demand deficit was so large that a voluntary distribution control was set up early in 1945, and on May 29, 1945, the War Production Board placed thallium chemicals under allocation. Schedule 107 of General Allocation Order M-300 covers thallium acetate, thallium chloride, thallium formate, and thallium sulfate. The sulfate is usually prepared from the metal but may be derived from the other compounds named. Foreign supplies were unavailable during the European war period, but in the late spring of 1945 about 3,000 pounds were acquired from Belgium and France. The Fish and Wildlife Service has been making field tests of substitute poisons, but their efficiency had not been demonstrated by May 1945. Thallium production was reported⁵⁴ from Canada for the first time. The Hudson Bay Mining & Smelting Co., Ltd., at Flin Flon, Manitoba, had an output in 1944 of 128 pounds valued at \$1,690.

⁵⁴ Dominion Bureau of Statistics, Preliminary Report of Canada's Mineral Production for the Calendar Year 1944: January 2, 1945, pp. 2, 5.

Methods of recovery from the dusts arising from the treatment of zinc ores or scrap were described.⁵⁵

Thallium metal was quoted by E&MJ Metal and Mineral Markets at \$10 a pound for the first 6 months of 1944, in the third quarter at \$12.50, and in the last quarter at \$12 a pound. Thallium sulfate (99 percent) has been quoted by the Oil, Paint, and Drug Reporter at \$12.50 a pound, f. o. b. works, since September 1942.

ZIRCONIUM

Domestic production.—The output of zircon in the United States in 1944 was again negligible in terms of requirements. The sole producer remained the Riz Mineral Co., which concentrated sand mined near Vero Beach, Indian River County, Fla. The Humphreys Gold Corp. early in 1944 leased the plant and property of the Rutile Mining Co. of Florida, a former producer of crude zircon concentrates from beach sands near South Jacksonville, Fla. The Humphreys Corp. expects to begin production of zircon in mid-1945 from tailings resulting from its ilmenite and rutile recovery operation.

Foreign trade.—Imports of zirconium concentrates in 1944 were 34 percent less than in 1943 and approximately one-half those in 1942. Distribution of foreign receipts by sources and classes of ore are given in the following table. Australian beach sand deposits were described.⁵⁶ During 1944 exports were: Ore and concentrates, 80 short tons (\$9,098); metal and alloys, 117 tons (\$100,040); and compounds, 233 tons (\$70,652).

Zirconium concentrates imported for consumption in the United States, 1940-44, by countries, in short tons¹

Year	Zircon from—				Baddeleyite from Brazil	Accessory titanium minerals ²	Total zirconium concentrates ³

1944.....	11,317	101	-----	11,418	2,231	10,384	24,033	576,299

¹ Totals and country break-down by the U. S. Department of Commerce. Mineral break-down by Bureau of Mines.

² Rutile and ilmenite content of mixed zirconium-titanium concentrates imported from Australia.

³ Classified as "ore" by U. S. Department of Commerce.

⁴ Zircon imports from Brazil, 1940-41, included with baddeleyite.

Consumption and uses.—Zircon shipments in 1944 to consumers rose to a new high of 14,484 short tons compared with 8,954 tons in 1943. Based on information furnished by the principal shippers, uses in 1944 were, in percentages, as follows: Electrical and chemical porcelains, 44; metal and alloys, 23; pottery glazes, 9; refractories, 9; porcelain enamels, 8; glass, 4; other 3. Iron Age stated⁵⁷ that about 1,000 pounds of pure, ductile zirconium were being made annually by deposition on a hot filament from the volatilized tetraiodide. This method of production was described by the Foote Mineral Co.⁵⁸

⁵⁵ Sanderson, L., Thallium: Canadian Min. Jour., vol. 65, No. 9, September 1944, pp. 624-625.

⁵⁶ Engineering and Mining Journal, Value of 1943 Mineral Output Drops—Queensland Beach Sands Mined for Zircon and Rutile: Vol. 145, No. 10, October 1944, pp. 164-165.

⁵⁷ Iron Age, Nonferrous Metallurgy: Vol. 155, No. 1, January 4, 1945, pp. 73-74.

⁵⁸ Raynor, W. M., Zirconium—an Abundant "Rare" Metal: Foote Prints, vol. 15, No. 2, summer, 1943, pp. 3, 6-8.

Zirconium hydride (ZrH_2) was advertised as a safe material for use in powder metallurgy for production of sintered alloys. The extreme explosibility of zirconium metal powder was described by the Bureau of Mines in 1943.

Stocks.—At the close of 1944 distributors' stocks of zircon (including zircon content of zirconium-titanium concentrates) were 4,550 short tons, a decrease of 3,647 tons during the year. Zirconium-ore imports had been Government-controlled (General Imports Order M-63) because the Australian material carries about 50 percent rutile and ilmenite; supplies of both were deficient. Since adequate supplies of rutile for essential uses became available during 1944, imports of rutile and zirconium were freed from that control October 1, 1944.

Prices.—Zirconium ore, 55 percent ZrO_2 , f. o. b. Atlantic seaboard, was quoted nominally at \$65-\$75 throughout the year by E&MJ Metal and Mineral Markets. The quoted prices for zirconium ferro-silicon, 12-15 percent zirconium, at \$102.50-\$107.50 per gross ton, and 35-40 percent zirconium at 14-16 cents a pound; and \$7 a pound for powdered zirconium metal, remained unchanged in 1944.

BITUMINOUS COAL AND LIGNITE ¹

SURVEY OF THE BITUMINOUS-COAL AND LIGNITE INDUSTRY IN 1944

The production of soft coal attained a new all-time high in 1944—an estimated output of 620,000,000 net tons³ compared with the previous peak of 590,177,069 tons in 1943. Although production was the greatest on record it still was not sufficient to meet the demand created by the expanding war economy. Labor difficulties caused several interruptions to production. According to the Bureau of Labor Statistics, there were 792 strikes in soft-coal mines in 1944, with 229,907 workers involved, 1,056,341 man-days lost (an average of 4.6 days per man), and an estimated loss in production of 6,000,000 tons. Difficulty in obtaining supplies and machinery and a shortage of men also caused a loss in output.

Production.—The outstanding feature related to the production of 620,000,000 tons in 1944 was the elimination of seasonal declines, due largely to the Government program urging consumers to accumulate stocks during the summer. Throughout most of the year production remained near 12,000,000 tons per week, except when output was reduced because of holidays.

Consumption.—Five of the major classes of consumers used more coal in 1944 than in 1943, and the other five used less. The total consumption in 1944 was approximately 4,000,000 tons less than in 1943. Table 5 shows the trends in consumption for the major classes of consumers.

¹ Data for 1944 are preliminary; detailed statistics with final revisions will be released later. Data for 1943 are final.

² Following United States usage, the term "trillion" in this report is equivalent to 1,000,000,000,000.

³ Throughout this chapter, "tons" refers to net tons of 2,000 pounds, unless otherwise indicated.

Changes in stocks.—The reserve supply of bituminous coal and lignite in the hands of industrial consumers and in retail coal yards increased from a total of 56,686,000 tons at the beginning of 1944 to 57,204,000 tons at the close. The average days' supply of stocks increased from 30 to 32. Stocks on the upper Lake docks increased 533,308 tons from January 1 to December 31, 1944.

Distribution.—Shipments of bituminous coal and lignite during 1944 showed increases in most of the channels of distribution compared with 1943. Table 10 shows trends in distribution of bituminous coal and lignite for 1938-44. Changes in the 1943-44 monthly volume of the more important movements are shown in figure 9.

FIGURE 1.—Trends of production, stocks, and prices of bituminous coal and lignite in the United States, 1935-44.

Mechanization.—The quantity of coal loaded mechanically at underground mines in the United States continued to advance during 1944. Mechanical loading increased from 48.9 percent of the total underground output in 1943 to an estimated 50.5 percent in 1944. Sales of underground loading equipment, in terms of capacity, were 6 percent greater than in 1943.

Mechanical cleaning.—The total capacity of mechanical-cleaning equipment sold for use at bituminous-coal mines in 1944 was estimated at 5,400 tons of cleaned coal per hour, an increase of 55 percent from the previous year.

Trend of employment.—An estimate of the average number of men employed at bituminous-coal and lignite mines in 1944 indicates a drop to 383,000 men from 416,007 in 1943.

Index to capacity.—The potential output upon a 308-day basis (6-day week, full-time capacity) was 689,000,000 tons in 1943. As it is not possible for all mines to operate 308 days per year, a more conservative figure of 280 days was suggested some years ago by the coal committee of the American Institute of Mining and Metallurgical Engineers (see Minerals Yearbook, 1935, pp. 631-632). The average output per day worked in 1943 was 2,235,519 tons, which (if applied

to 280 days) gives an annual potential output of 626,000,000 tons compared with the actual total production of 590,177,069 tons. For purposes of historical comparison a capacity at 261 days, based on the 5-day week, is also shown in figure 4 and in tables 12 and 13.

Trend of fuel efficiency.—For many years before 1942 there was a steady trend toward increased fuel efficiency. During the period 1942–44 this trend was arrested or reversed, and some industries exhibited decreased fuel efficiency (see table 6).

Competition of oil and gas.—In 1944, as in 1943, competition between the various fuels was far outweighed by the urgent need for adequate production of all fuels to satisfy the continued increase in demand.

Electric power utilities consumed 3 percent more bituminous coal, 16 percent more fuel oil, and 18 percent more gas than in 1943.

FIGURE 2.—Production of bituminous coal and lignite in the United States, by weeks, 1942–44.

Class I railroads increased their consumption of coal 1 percent in 1944, while their purchases of fuel oil decreased from 1943 purchases by 2 percent.

Further curtailment of the manufacture of domestic coal-burning equipment is reflected by statistics published by the Bureau of the Census. Factory sales of domestic stokers were reduced from 4,460 in 1943 to 1,714 in 1944. However, shipments of domestic oil burners, boiler-burner units, and furnace-burner units increased from 27,956 in 1943 to 45,752 in 1944.

SOURCES OF DATA

Bituminous-coal and lignite production statistics for 1944 are preliminary estimates based upon (1) weekly or monthly reports of railroad carloadings of coal and beehive coke by all the important carriers, (2) shipments by river as reported by the United States Army Engineers, (3) direct reports from a number of mining companies, and

FIGURE 8.—Average production of bituminous coal and lignite in the United States per working day in each month, 1922-44.

(4) monthly production statements compiled by a number of local operators' associations and State mine departments. In the estimates for 1944, allowance has been made for commercial truck shipments, local sales and colliery fuel, and small trucking or wagon mines producing over 1,000 tons a year.

Data for 1943 are final and are based upon detailed annual reports of production and mine operation furnished by the producers. As in previous years, all but a small percentage of the output was covered by the reports submitted. For the remaining output not directly reported—consisting chiefly of small mines—it has been possible to obtain reasonably accurate data from the records of the State mine departments, which have statutory authority to require such reports, or, in a few instances, from railroad carloadings.

Final figures of employment obtained from the annual canvass of production as shown in this report for 1943 differ slightly from the estimated total of employment based on the sample monthly canvass of accidents as published October 27, 1944, in Mineral Industry Surveys HSS 341. According to the annual canvass, the average number of men employed amounted to 416,007, whereas, according to the monthly sample raised to 100 percent, the average number employed was 414,700. The major cause for this slight discrepancy was that one figure represented a complete canvass and the other was based upon less complete returns.

In accordance with the practice followed by the Bureau of Mines in previous years, the statistics in this report relate to mines having an output of 1,000 tons a year or more and do not attempt to include many small mines producing less than 1,000 tons a year that sell their output by wagon or truck.

These data include, for convenience and historical comparison, the small output of anthracite and semianthracite produced outside Pennsylvania and the production of lignite.

SALIENT STATISTICS

TABLE 1.—*Salient statistics of the bituminous-coal and lignite industry in the United States, 1943-44*

[All tonnage figures represent net tons]

	1943	1944 (preliminary)	Change in 1944
Production	590,177,069	620,000,000	Percent +5.1
Consumption in the United States ¹	594,517,000	590,694,000	— .6
Stocks at end of year:			
Industrial consumers and retail yards	56,686,000	57,204,000	+ .9
Stocks on upper Lake docks	5,629,410	6,162,718	+9.5
Unbilled loads, at mines or in classification yards ²	44,000	38,000	—13.6
Price indicators (average per net ton):			Cents
Average cost of railroad fuel purchased, f.o.b. mines ³	\$2.42	\$2.65	+23
Average cost of coking coal at merchant byproduct ovens ⁴	\$5.21	\$5.43	+22
Average retail price—35 cities ⁵	\$9.94	\$10.27	+33
Average railroad freight charge per net ton ⁶	\$2.30	\$2.21	—9
Underground loading machinery sold: ⁷			Percent
Mobile loading machines (number)	234	282	+20.5
Scrapers (number)	13	20	+53.8
Conveyors, including those with duckbills (units)	798	580	—27.3
Surface stripping	79,685,175	95,000,000	+19.2
Mechanically loaded underground	249,805,214	265,000,000	+6.1
Mechanically cleaned	145,575,849	150,000,000	+3.0
Average number of men employed ⁸	416,007	383,000	—7.9
Fuel-efficiency indicators:			
Pounds of coal per kw.-hr. at electric power plants ⁹	1.31	1.30	— .8
Pounds per 1,000 gross ton-miles—railroads ¹⁰	114	115	+ .9

¹ Represents certain classes of consumers only. See table 5 for consumers included.² Association of American Railroads.³ Interstate Commerce Commission (class I steam railways, including class I switching and terminal companies). Excludes freight charges.⁴ As reported by coke operators.⁵ Bureau of Labor Statistics.⁶ Average receipts per net ton of revenue bituminous coal and lignite originated, as reported by the Interstate Commerce Commission.⁷ Young, W. H., and Anderson, R. L., *Mechanization Sales: Coal Age*, February 1945, pp. 104-106, and *Min. Cong. Jour.*, February 1945, pp. 40-42.⁸ The figure for 1943 is based upon reports of mine operators producing over 1,000 tons. The figure for 1944 is estimated from various sources.⁹ Federal Power Commission.¹⁰ Interstate Commerce Commission; includes coal equivalent of fuel oil consumed.

PRODUCTION BY WEEKS AND MONTHS

The following tables summarize the preliminary statistics of weekly and monthly production of bituminous coal and lignite in 1944. The figures are estimates based upon daily and weekly statements of cars of coal and beehive coke loaded by the principal railroads and of shipments over the more important originating rivers. Allowance has been made for commercial truck shipments, local sales, and colliery fuel. The estimates given are based upon the latest information available and differ in some instances from the current figures previously published in the Weekly Coal Reports.

For method used in counting holidays, see chapter on Coal in Mineral Resources of the United States, 1930, page 631.

¹ Figures represent output and number of working days in that part of week included in calendar year shown. Total production for week of Jan. 1, 1944, was 10,515,000 tons.

² Average daily production for entire week and not for working days in calendar year shown.

TABLE 3.—Estimated monthly production of bituminous coal and lignite in the United States, by States, in thousands of net tons, in 1944

[Bituminous coal and lignite figures are preliminary estimates based on railroad carloadings and river shipments of coal and beehive coke, supplemented by direct reports from a number of mining companies, local coal operators' associations, and detailed monthly production statistics compiled by the State Mine Departments of Colorado, Illinois, Pennsylvania, Washington, and West Virginia. In making the estimates, allowance is made for commercial truck shipments, local sales, and colliery fuel, and for small trucking mines producing over 1,000 tons a year. The estimates here given differ in a few cases from the monthly figures previously published in the Weekly Coal Reports.]

State	January	February	March	April	May	June	July	August	September	October	November	December	Total

1944 ¹	2,850	78,883	132,049	10,931	94,654	10,734	1,545	8,789	130,353	124,906	590,694

¹ These data have been assembled to show changes in consumption of bituminous coal and lignite by such classes of consumers as report currently. The total, including retail deliveries, does not represent grand total consumption in the United States. Bunker-fuel statistics are not available for publication at present. Owing to the omission of bunker fuel, to revisions in data covering production, exports, and imports, and to unavoidable irregularities that occur in reports from respondents who are unable to require that definitions applied and closing dates observed by their accountants be identical with those generally used in the surveys of bituminous coal and lignite consumption, the "total of classes shown" for each year in the above table cannot be reconciled with the calculated consumption obtained by the formula: "Production plus imports minus exports plus or minus net changes in consumers' stocks."

² Geological Survey and Federal Power Commission. Represents bituminous coal and lignite consumed by public utility power plants in power generation, including a small quantity of coke amounting to approximately 100,000 tons annually.

³ Association of American Railroads. Represents consumption of bituminous coal and lignite by class I railways for all uses, including locomotive, powerhouse, shop, and station fuel. The Interstate Commerce Commission reports that in 1943 consumption for all uses by class I line-haul railways plus purchases for class II and class III railways, plus purchases by all switching and terminal companies combined, was 125,788,769 tons of bituminous coal and lignite. Similar data from the Interstate Commerce Commission are not yet available for 1944.

⁴ Estimates based upon reports collected by the Solid Fuels Administration for War from a selected list of representative manufacturing plants.

⁵ Subject to revision.

FIGURE 5.—Consumption of bituminous coal and lignite, by consumer class, with retail deliveries in the United States, 1935-44.

FUEL EFFICIENCY

TABLE 6.—Indicators of effect of fuel economy on consumption of coal in the United States per unit of performance since the World War of 1914-18

	Pounds	Reduction from base period (percent)
Steam railroads:		
Pounds per 1,000 gross ton-miles freight service:		
Average:		
1919-20	170	
1943	114	32.9
1944	115	32.4
Pounds per passenger-train car-mile:		
Average:		
1919-20	18.5	
1943	15.0	18.9
1944	14.8	20.0
Electric public-utility power plants:		
Pounds per kilowatt-hour:		
1919	3.2	
1943	1.5	59.4
1944	1.3	59.4
Iron and steel—pounds coking coal per net ton of pig: ¹		
1918	3,194	
1943	2,620	18.0
1944	2,629	17.7
Coke manufacture: Savings of heat values through recovery of gas, tar, light oils, and breeze by extension of byproduct in place of beehive coking, 1913-14, expressed as percent of coal used for all coke in 1944: ²		18.5

¹ Includes only savings through higher yields of merchantable coke per ton of coal charge and lower consumption of coke per ton of iron. Excludes economies through recovery of byproducts, which are covered in next item.

² These byproducts are used in part for boiler fuel, in part for metallurgical purposes, in part for domestic heating and coking, and to a small extent for automotive fuel.

FIGURE 6.—Trends in fuel efficiency in the United States, 1915-44.

RELATIVE RATE OF GROWTH OF COAL, OIL, AND WATER POWER, 1889-1944

The total supply of available energy in the form of coal, oil, natural gas, and water power in 1944 was 35,707 trillion B. t. u.—a 5.6-percent increase over 1943 (see fig. 7).

The figures are expressed in British thermal units because some common denominator is necessary for such unlike quantities as tons of coal, barrels of oil, and cubic feet of gas. Table 7 summarizes the equivalent of each of the fuels in trillions of British thermal units. Water power is represented by the equivalent fuel required to perform the same work. The table covers the years since 1935. Details for 1889 to 1934 are given in Minerals Yearbook, 1937, page 807.

In converting water power to its fuel equivalent, two alternative assumptions have been made. The first, as in previous issues of these tables, assumes a *constant* fuel equivalent of 4.02 pounds of coal for each kilowatt-hour of water power produced throughout the entire period from 1889 to 1944. This factor was selected because it represents, in round numbers, the average efficiency of all central stations generating steam-electric power in 1913, the base period used. The usefulness of the *constant* factor lies in showing the rate at which water power is being developed. It permits direct comparison between the relative increase (in kilowatt-hours of water power) and the corresponding increase or decrease (in tons of coal, barrels of oil, or cubic feet of gas produced). On the other hand the *constant* factor makes no allowance for the fact that coal and other fuels produced today are used more efficiently than formerly.

To show the influence of improving fuel efficiency, a second computation of the energy equivalent of water power has therefore been made. This assumes a *prevailing* fuel equivalent, diminishing year by year, which represents the average performance of all fuel-burning central electric stations for the year in question. This average has declined from about 7.05 pounds of coal per kilowatt-hour in 1899 to 1.30 pounds in 1944. (The *prevailing* factor is thus much above the *constant* factor in 1899 and much below it in 1944.) The *prevailing* fuel equivalent indicates more nearly the quantity of fuel that would have been needed in any one year to generate the same power in a steam-electric station. It should be noted, however, that the ultimate uses to which the water power generated is put often displace fuel burned much less efficiently than in central stations and that in any instance no other important branch of fuel consumption has made advances in fuel efficiency approaching that of the central stations.

As these tables attempt to determine the total energy from all fuels and from water power, the ideal factor for converting water power into fuel equivalent would be the average efficiency of all forms of fuel consumption in each year. No basis for determining such an all-embracing average exists at present, but enough is known to make certain that it would show much less reduction from 1899 to 1944 than do the central stations. For the present, a just comparison of the changing contributions of water power and of fuel to the national energy supply would lie somewhere between the results shown by the *constant* equivalent and the *prevailing* central-station equivalent in these tables.

As in earlier issues of these tables, the figures for oil and natural gas represent the entire production of crude petroleum and of gas. Most of this production does not come into direct competition with coal. Much of the supply of both oil and gas is used in regions of the country, such as California and portions of the Southwest, where coal is available only at unusually high cost because of heavy transport charges. Nearly half of the natural gas is used in the field for drilling or operating oil and gas wells and pipe lines or for the manufacture of carbon black. More than half the oil is used in the form of gasoline, kerosine, and lubricants, for which purposes coal cannot well compete, except at very much higher levels of oil prices. Even these refined products, however, involve a certain measure of indirect competition with coal, for the energy market of the country is becoming more fluid and competitive, and a demand that cannot be met by one source of supply tends to fall back on the others.

The subject of interfuel competition is exceedingly complex, and an elaborate analysis and the accumulation of data not now available would be required to determine even approximately how much of any one fuel actually has been displaced either by other fuels or by water power. The present tables do not permit determination of such displacement; their purpose is rather to measure the long-time trends in the total demand for energy.

FIGURE 7.—Annual supply of energy from mineral fuels and water power in the United States, 1889-1944

FIGURE 8.—Percentage of total B. t. u. equivalent contributed by the several sources of energy in the United States, counting water power at constant fuel equivalent, 1889-1944. If water power is counted at the prevailing fuel equivalent of central stations in each year, its proportion is 3.2 percent in 1889 and 3.9 percent in 1944, and the proportions of the other sources of energy are affected accordingly.

TABLE 7.—Annual supply of energy from mineral fuels and water power in the United States, 1935-44,¹ in trillions of B. t. u.²

Year	Pennsylvania anthracite	Bituminous coal and lignite	Total coal	Petroleum (total crude, including that refined)		Natural gas (total production)	Total petroleum and natural gas	Total mineral fuels	Water power (fuel equivalent)		Grand total energy

1941.....	1,533	13,471	15,004	8,413	304	3,024	11,741	26,745	2,804	934	29,549	27,679
1942 ⁵	1,641	15,267	16,908	8,320	(⁶)	3,282	11,602	28,510	3,485	1,136	31,995	29,646
1943 ⁵	1,650	15,463	17,113	9,034	(⁶)	3,671	12,705	29,818	3,999	1,304	33,817	31,122
1944 ⁵	1,753	16,244	17,997	10,067	(⁶)	3,654	13,721	31,718	3,989	1,288	35,707	33,006

¹ Comparable data for earlier years in Minerals Yearbook, 1937, p. 807.² The unit heat values employed are: Anthracite, 13,600 B. t. u. per pound; bituminous coal and lignite, 13,100 B. t. u. per pound; petroleum, 6,000,000 B. t. u. per barrel; natural gas, 1,075 B. t. u. per cubic foot. Water power includes installations owned by manufacturing plants and mines, as well as Government and privately owned public utilities. The fuel equivalent of water power is calculated from the kilowatt-hours of power produced wherever available, as is true of all public-utility plants since 1919. Otherwise, the fuel equivalent is calculated from the reported horsepower of installed water wheels, assuming a capacity factor of 20 percent for manufacturers and mines and of 40 percent for public utilities.³ Assuming 4.02 pounds per kilowatt-hour, which is the average of central electric station practice in 1913, the base period used.⁴ Assuming the average central-station practice for each of the years for which data are available, which declined from about 7.05 pounds per kilowatt-hour in 1899 to 1.30 pounds in 1944.⁵ Subject to revision.⁶ Excludes imports of crude petroleum. Figures not available for publication.TABLE 8.—Index numbers for relative rate of growth of coal, oil, and water power in the United States, 1935-44,¹

POSTWAR OUTLOOK

The postwar outlook for soft coal revolves around the general level of industrial activity and the extent of competition offered by other fuels. The consumption of soft coal follows very closely the trend of industry, as only a small fraction of the total is used for domestic space-heating. The accumulated demand for many products, particularly for automobiles, machinery, building materials, and household appliances, doubtless will stimulate industry for several years after the war closes. However, it is expected that inroads on coal by competitive fuels will be resumed.

Soft coal will be in a vulnerable competitive position very soon. The shortage of coal has already resulted in some reconversion to fuel oil. A very rapid expansion of natural-gas consumption is anticipated as soon as pipe becomes available. Plans are already under way for vast hydroelectric developments after the war. It is not too early for the soft-coal industry to begin to prepare itself for the inevitable postwar competitive struggle.

FINAL BITUMINOUS-COAL AND LIGNITE STATISTICS FOR 1943

Tables 12 to 49 give the final detailed statistics of bituminous-coal and lignite-mine operations in 1943. The subjects covered include production, number and size of mines, employment, value, mechanization, exports, and world production.

Figure 10.—Trends of employment, mechanization, and output per man at bituminous-coal and lignite mines in the United States, 1900-1944.

SALIENT TRENDS

† The total production differs from sum of items shown by amount of changes in inventory and tonnage not accounted for in distribution analysis. This amounted to 596,113 tons.

‡ Includes 202,337 tons of coal reported as net changes in stocks at mines, Jan. 1, 1939, to Jan. 1, 1940.
 § Data not available.
 ¶ Includes central washeries operated by consumers.

‡ In 1937, coal loaded at mine for shipment by water is included with "Loaded at mine for shipment by rail."
 § Coal "Taken by locomotive tenders at tippie," "Shipped by conveyor or tram to point of consumption," and "Used by mine employees" included with "Shipped by truck or wagon."
 ¶ In 1936 data were not collected in such form as to permit a separation of coal "Taken by locomotive tenders at tippie," "Shipped by conveyor or tram to point of consumption," and "Used by mine employees." They are all included here under "Used by mine employees."

¹ Data not available.² Percentages for years 1890 to 1913, inclusive, are of total production, as separation of strip-mine and underground production not available for those years.³ For years 1906 to 1926, inclusive, percentages are exclusive of coal cleaned at central washeries operated by consumers; after 1926, when data became available on tonnage cleaned by consumer-operated plants, percentages include total tons cleaned at mines and at consumer-operated washeries.⁴ One-half day or less.

SUMMARY BY STATES AND DISTRICTS
TABLE 15.—Number of mines, production, value, employment, days active, man-days, and output per man per day at bituminous-coal and lignite mines in the United States, by States, in 1943
 [Exclusive of mines producing less than 1,000 tons]

State	Num-ber of active mines	Disposition of coal produced (net tons)										Average number of employees				Aver-age num-ber of days mines were active	Number of man-days worked	Aver-age tons per man per day
		Loaded at mine di-rectly into railroad cars or river barges	Hauled by truck to railroad siding for shipment by railroad or by water-way for shipment by water	Shipped by truck or wagon (exclud-ing coal used by mines employ-ees)	Taken by loco-mo-tive tenders at tipples	Shipped by con-veyor or train to point of con-sump-tion	Used by mines employ-ees	Used at mines for power and heat and made into beet-licoleat mines	Total quantity	Aver-age value per ton	Surface		Total					
											Under-ground	In strip pits		All others

¹ Includes coal hauled by truck to waterway for shipment by water in following States in 1943: Alabama, 6,492 tons; Illinois, 66,742; Kentucky, 8,300; Ohio 69,219; Pennsylvania, 121,839; Tennessee, 100,696; and West Virginia, 524,138—a grand total of 897,126 tons.

² Includes coal made into beehive coke at mines in following States in 1943: Colorado, 153,762 tons; Kentucky, 34,024; Pennsylvania, 6,879,800; Tennessee, 6,479; Utah, 81,839; Virginia, 496,430; and West Virginia, 663,840—a grand total of 8,185,254 tons.

³ Value received or charged for coal f. o. b. mine, including selling cost. (Includes a value for coal not but used by producer, such as mine fuel and coal coked [not coke] as estimated by producer, at average prices that might have been received if such coal had been sold commercially.)

⁴ As it is necessary to conceal certain items in the lignite break-down of disposition of coal, the figures are shown here in column where greater part of concealed tonnage is included.

TABLE 16.—Number of mines, production, value, employment, days active, man-days, and output per man per day at bituminous-coal and lignite mines in the United States, by districts, in 1943

¹ Figures represent output and number of working days in that part of week included in calendar year shown. Total production for week of Jan. 2, 1943, was 9,479,000 tons and for Jan. 1, 1944, was 10,515,000 tons

² Average daily production for entire week and not for working days in calendar year shown.

TABLE 18.—Coal production in the United States, in 1943, by States (final figures), with estimates by months, in thousands of net tons

(Totals for year are based on final complete returns from all operators known to have produced more than 1,000 tons a year. The apportionment of known yearly total among the twelve months is based upon best information available; in some States upon direct tonnage reports by operators to State mine departments; in most cases upon current records of railway carloadings and waterway shipments.)

AVERAGE VALUE

Before the Bituminous Coal Act of 1937 was passed, the most valuable single index of the trend of prices at the mines was the "average value per ton, f. o. b. mines," as given in the familiar annual coal reports of the Bureau of Mines, United States Department of the Interior. This series was referred to in Bureau of Mines reports as representing "bituminous coal," and it covered all coal (other than Pennsylvania anthracite) produced in the United States. It represented the bituminous-coal industry as the term ordinarily was used in the trade and included the lignite of the Dakotas, Texas, and Montana, as well as any small tonnages of hard coal produced outside of Pennsylvania.

With the passage of the Coal Act, the Bureau of Mines relinquished the collection of statistics relating to bituminous coal, effective June 30, 1937, though continuing to compile data regarding lignite and Pennsylvania anthracite. Effective the same date, the Coal Commission became responsible for the compilation of data on bituminous coal, though not attempting to collect data regarding lignite, which was specifically exempted by the Act. The records of the Commission (later the Bituminous Coal Division, United States Department of the Interior) relate to all coal other than Pennsylvania anthracite, Virginia semianthracite, and lignite.

To permit comparison of the old and new series, therefore, it is necessary to separate the lignites from the bituminous coals, though the combined average for the two is continued in a form as nearly comparable as possible with the old series. (See table 20).

A more important change in the two series relates to the treatment of selling expenses. The old Bureau of Mines series of "value at the mines" excluded the selling cost. Reporting operators were asked to state the "Amount received at the mines f. o. b. cars less the selling expense." No details were asked regarding the items included in the value, and no systematic effort was made to follow up the exclusion of selling expenses. It was realized at the time that some producers might find it impractical to exclude selling costs and that some part of the selling expenses of the industry might be included in the results. Nevertheless, the reports were checked for consistency from year to year, the questions were retained in the same form without change, and the results are believed to have been comparable from one year to the next. The new series of the Coal Commission represents the total or gross realization on all coal produced and specifically includes the selling cost.

The two sets of data may not be precisely comparable with respect to coal produced but not sold on the commercial market. In the Bureau of Mines series reporting operators were instructed that the "value of coal not sold but used by producer, also mine fuel and coal made into coke, should be estimated at average prices that might have been received." The instructions of the Coal Commission regarding such items were in effect similar, though given in greater detail.

A comparison of the two series is possible for 1936. In that year the average value per ton on the old (Bureau of Mines) basis amounted to \$1.761 per ton for bituminous coal, excluding lignite. The average gross realization, according to data collected by the Coal Commission,

was \$1.831 per ton. The difference amounts to \$0.07 per ton—an amount somewhat less than the average selling expenditure computed per ton of all coal produced, as reported to the Coal Commission. The comparison confirms previous indications that the great majority of operators reporting in earlier years had followed instructions and omitted selling expenses in computing the average value but that some of them had included the selling expense. The change in method of reporting should be kept in mind in comparing the two sets of data. As the reports to the Commission were submitted on a detailed accounting return and made under oath, they are to be accepted. The returns of earlier years, upon a voluntary basis and not in all instances uniform as to treatment of selling costs, seem to have been thoroughly comparable from one year to the next and afford the best available index to the rise and fall of the mine prices received by operators down to 1936.

TABLE 20.—Trend of average value in the United States of bituminous coal and lignite per ton, f. o. b. mines, 1929–43

Year	Bituminous coal (subject to regulation under 1937 Act) ¹	Lignite ²	Total
Average value per ton less selling cost:			
1929.....	\$1.782	\$1.548	\$1.781
1930.....	1.702	1.556	1.701
1931.....	1.542	1.410	1.541
1932.....	1.313	1.313	1.313
1933.....	1.337	1.188	1.336
1934.....	1.751	1.387	1.749
1935.....	1.772	1.120	1.767
1936.....	1.761	1.061	1.756
Average gross realization, selling cost not deducted:			
1936.....	1.831	³ 1.061	1.826
1937.....	1.946	³ 1.080	1.939
1938.....	1.955	³ 1.071	1.947
1939 ⁴	1.850	1.158	1.845
1940.....	1.913	³ 1.156	1.908
1941.....	2.194	1.237	2.189
1942.....	2.363	1.364	2.358
1943.....	2.691	1.490	2.685

¹ Includes all coal produced other than Pennsylvania anthracite and the lignite included in the second column.

² North Dakota, South Dakota, and the lignite counties of Montana and Texas.

³ Figures for 1936–38 and 1940 exclude selling cost as before.

⁴ Producers were asked to exclude selling cost in reporting value, but a number of them included such costs.

LABOR STATISTICS

Men employed.—An average of 416,007 men was employed at bituminous-coal mines in 1943, a 10.0-percent decrease from the total of 461,991 for 1942. (See fig. 10.)

The method used here in calculating employment gives an accurate measure of the working force in the coal industry, but it does not consider the time lost by men on the rolls through intermittent operations. To measure the influence of intermittency upon employment, the factor of mine activity as indicated by the average number of days of plant operation was recorded separately. The average number of men employed when the mines were in operation was then used, in conjunction with the average number of days of operation, as a measure of the total volume of employment in the industry.

Days operated.—The average number of days of operation at bituminous-coal mines in 1943 was 264. This represents an increase over the average of 246 days for 1942. All statistics on days of mine operation included in this report are weighted averages, in which the operating time of each mine has been weighted by the number of its employees. Several coal-mining States publish series on the number of days worked that are simple averages of the figures for each reporting mine, regardless of size. As these unweighted averages are likely to be unduly depressed by small mines, which generally operate fewer days than the larger ones, they tend to understate the working time of a typical mine employee.

Man-days of labor.—Only a small proportion of the bituminous-coal-mine operations, however, keep an accurate record of man-days or man-hours worked. Consequently, man-days have been computed by multiplying the number of workers employed by the number of operating days. Although these computations were made for each individual mine, the combined total is necessarily only an approximation.

Until the American coal industry arranges to keep an accurate record of man-days or man-hours of employment, all computations of accident rates, daily earnings, and output per man will remain subject to qualification. Meanwhile, the method of multiplying men by days must be accepted as the best available procedure.

Data for 1943 indicate that bituminous-coal-mine employees performed 109,708,871 man-days of labor during the year. Table 15 gives a summary record of men employed, days operated, and output per man per day at bituminous-coal mines, by States, in 1943. Details by counties for 1943 are shown in table 41.

Length of working day.—Table 21 summarizes the replies of mine operators to the question, "Number of hours operated per shift."

The established working day does not of itself measure the length of time that men actually work or the time that they are underground, because of the possibility of overtime, because the mine may sometimes shut down before the full day is over, because the miner may go home before the mine stops, and because he spends considerable time going to and from his place of work underground. These figures represent the operator's statement of the nominal operating day for the mine. They do not purport to represent the time actually worked by the men. On the one hand, they make no allowance for tonnage of piece workers who leave early; on the other hand, they make no allowance for tonnage men who continue at work after the mine as a whole is shut down or who go into the mine to work on days when the tippie is idle.

It was found that 73.8 percent of the men employed were in 7-hour mines and that the weighted average working shift was 7.23 hours.

Shipped by conveyor or tram to point of consumption.....		7, 476, 717	7, 476, 717
Coal used by employees.....		2, 549, 775	2, 549, 775
Used at mine for power and heat.....		2, 701, 828	2, 701, 828
Made into beehive coke at mine.....		8, 185, 254	8, 185, 254
Total production.....		590, 177, 069	590, 177, 069

¹ Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding for shipment by rail, and hauled by truck to waterway for shipment by water. In general, figures show quantity of bituminous coal and lignite originated for each railroad and waterway as reported by mine operators. It must be noted that in one year an operator may report coal loaded on subsidiary railroad and in another year same operator may report coal loaded on parent railroad system.

² Tonnage from North Dakota lignite mines shipping on Great Northern Railway included with that shipped on Minneapolis, St. Paul, & Sault Ste. Marie Railway.

³ Tonnage from Texas lignite mines shipping on Rockdale, Sandow, & Southern Railroad and St. Louis Southwestern Railway Co. of Texas included with that shipped on Missouri-Kansas-Texas Railroad.

METHODS OF RECOVERY
TABLE 23.—Bituminous coal and lignite mined by different methods in the United States, by States, in 1943

State	From underground workings						From strip pits		Grand total production (net tons)

MECHANICAL LOADING

Devices for loading coal mechanically in underground bituminous-coal and lignite mines are divided into two types: Those that completely mechanize the loading, practically eliminating hand shoveling, and those that greatly reduce the labor involved in hand shoveling. Devices in the first category include mobile loaders, scrapers, and self-loading conveyors or duckbills and are designated as "machines." Those in the second category include all types of hand-loaded face conveyors and pit-car loaders and are designated as "conveyors."

During 1938, the first year complete data were available on mechanical loading by types of devices, 68 percent of the underground mechanically loaded tonnage was loaded by "machines" or mobile loaders, scrapers, and duckbills, and 32 percent was handled by "conveyors" or hand-loaded conveyors and pit-car loaders. In 1943 these percentages were 81 percent for "machines" and 19 percent for "conveyors."

The following tables (28 to 33, inclusive) showing detailed statistics on mechanical loading pertain only to underground mines and do not include strip mines or data on coal handled on the surface.

Sales of mechanical loading equipment in 1944.—The estimated capacity of mechanical loading equipment sold for underground use in all coal mines was 6 percent more in 1944 than in 1943. Table 28 shows the sales reported, by type of equipment, and the number of manufacturers reporting for 1937-44.

Sales of conveyors to bituminous-coal and lignite mines in 1944 totaled 580 units. The figures for 1942-44 exclude duckbills, which were included in all previous years. Therefore, these sales are not comparable with those for 1941 or earlier years. By excluding sales of duckbills, some of the overlapping sales of conveyors were eliminated. However, it appears that a certain amount of overlapping remains; for instance, in 1942 there were 4,103 conveyors (hand-loaded and those equipped with duckbills) in active use in bituminous-coal and lignite mines, as reported by mine operators. By adding 1942 conveyor sales of 1,167 units, 5,270 units appeared available for use in 1943, whereas the actual number reported in use by mine operators was 4,417, or 853 less. This difference represents idle or worn-out and obsolete equipment, duplications in reporting sales, and a small number of conveyors used in conjunction with mobile loaders.

The number of mobile loaders, scrapers, and conveyors (shipped into the various States and groups of States in 1944) and the number of units in actual use in 1943 are shown in table 30.

Statistics on mechanical loading in bituminous-coal and lignite mines in 1943.—During 1943 the approximate percentage of the tonnage loaded by each type of equipment was as follows: Mobile loaders, 72; hand-loaded conveyors, 17; duckbills, 9; pit-car loaders, 1; and scrapers, 1.

Mobile loaders handle more coal than all the other types of mechanical loading devices combined. Where coal is loaded by mobile loaders it is most commonly loaded directly into mine cars, but some tonnage is loaded into shuttle cars or onto conveyors. During 1943, 80 percent of the bituminous coal and lignite handled by mobile loaders was

loaded into mine cars, 17 percent into shuttle cars, and 3 percent onto conveyors.

During 1943 in underground bituminous-coal and lignite mines 2,525 mobile loaders handled 179,008,477 tons—an average of 70,894 tons per mobile loader per year; scrapers averaged 16,258; pit-car loaders, 8,314; duckbills, 18,692; and hand-loaded face conveyors, 13,746 per year per unit for the same period (see tables 29 and 31).

Mechanical loading, by States.—West Virginia has been the leading producer of mechanically loaded coal since 1939. During 1943 West Virginia produced 74,517,853 tons of mechanically loaded coal, followed by Illinois with 47,420,744, Pennsylvania with 42,653,020, Kentucky with 19,583,421, and Ohio with 15,320,808 tons. These five States produced 80 percent of the total output of underground mechanically loaded bituminous coal in the United States in 1943.

Detailed data, by States, on the number of mines and machines and the production of mechanically loaded coal compared with the total production at mines using mechanical loading devices are given in table 32. Comparative changes in underground mechanical loading in 1942–43, by States, are shown in table 33.

Table 34 shows bituminous coal and lignite mined by stripping compared with underground hand-loaded and machine-loaded tonnage, by States, for 1943.

TABLE 28.—Units of mechanical loading equipment sold to bituminous-coal and lignite mines for underground use in the United States, as reported by manufacturers, 1937–44

MECHANICAL CLEANING

In 1927, the first year complete data were collected on mechanical cleaning of bituminous coal, 5 percent (27,692,047 tons) of the total output was cleaned. This percentage has increased each year, and in 1943 almost 25 percent was cleaned.

Reports on sales of bituminous-coal-cleaning equipment show that installations were made in 12 States in 1944 compared with 10 States in 1943. It was estimated that the 1944 sales of cleaning equipment increased the capacity for bituminous-coal cleaning by 5,400 tons of cleaned coal per hour compared with an increase of 3,500 tons in 1943.

Tables 35, 36, 39, and 40 include mechanical cleaning data on all coal mined in the United States except Pennsylvania anthracite. Tables 37 and 38 are upon the same basis but do not include consumer-operated plants. There are no mechanical cleaning plants at lignite mines.

Consumer-operated plants include plants owned by steel companies which receive coal from various mines (but usually from affiliated companies), clean it, and then consume it directly at the plant.

Coal cleaned at consumer-operated plants was tabulated in the State where the plant was located. All coal cleaned at plants other than consumer-operated plants was included in the State from which the coal was mined.

Table 35 compares bituminous coal cleaned in 1940-43, inclusive, by method of cleaning. Both wet and pneumatic methods increased in 1943 over 1942.

Mechanical cleaning by types of equipment.—The quantity of bituminous coal cleaned by wet-washing methods reached 124,374,775 tons in 1943—an increase of 1.9 percent over 1942. The quantity cleaned by pneumatic methods was 21,201,074 tons—an increase of 5 percent.

Table 36 compares the number of cleaning plants and tons of cleaned coal, by types of equipment, for 1942 and 1943. During 1943, 403 wet-washing and 83 pneumatic cleaning plants were in operation. Fifty-four tipples used both wet and dry methods at the same plant; deducting these duplications gives a net total of 432 plants that cleaned coal in 1943 compared with 438 in 1942.

Wet methods of cleaning coal include piston- or common-type jigs, Baum-type jigs, concentrating tables, and launders and upward-current classifiers, and any combinations of these four methods. Baum-type jigs cleaned approximately 39 percent of the total coal cleaned by wet methods during 1943.

Pneumatic methods of coal cleaning include air tables, air flow, and air sand, and any combinations of these three methods. During 1943 air tables cleaned 63 percent of the coal cleaned by pneumatic methods.

Mines served by cleaning plants, exclusive of those that ship to washeries operated by steel companies, produced 222,898,414 tons or 37.8 percent of the total bituminous output in 1943. In this same group of mines, 135,608,665 tons were mechanically cleaned; therefore 60.8 percent of the coal produced at mines with cleaning plants in 1943 was cleaned at the mine. The rest of the output (39.2 percent) presumably represents the larger sizes commonly picked by hand.

Table 37 shows total production of coal at mines with cleaning plants by methods of preparation in 1942 and 1943.

Coal cleaning by States.—The following States led in volume of coal mechanically cleaned in the United States in 1943: Pennsylvania, 24.3 percent of total; West Virginia, 21.7; Illinois, 20.8; Alabama, 9.2; and Indiana, 6.6 percent. These five States accounted for 82.6 percent of the total mechanically cleaned coal in 1943. Table 39 shows the number of plants in operation, tons of clean coal, and percentage of State output mechanically cleaned in 1942 and 1943.

Relation between raw coal, clean coal, and refuse.—For every 100 tons of raw coal cleaned during 1943 at the mines, 86.5 tons of clean merchantable coal, on an average, were obtained, and 13.5 tons of refuse were discarded. Table 40 shows total production of mines with cleaning plants and results of cleaning operations, by States.

Methods of mining at mines served by cleaning plants.—Mechanical loading, both in underground mines and strip pits, appears to be closely related to mechanical cleaning. Table 38 shows the mining methods at mines having cleaning plants. Production of coal from strip mines in 1943 was 79,685,175 tons (see table 34), of which 30,326,426 tons (38.1 percent) came from strip mines having mechanical cleaning tipples. Underground coal loaded mechanically in 1943 totaled 249,805,214 tons, of which 125,313,683 tons (50.2 percent) passed through tipples equipped with mechanical-cleaning devices. Hand-loaded underground coal production in 1943 totaled 260,686,680 tons, of which 25.8 percent passed through tipples equipped with leaning plants.

TABLE 35.—*Bituminous coal mechanically cleaned by wet and pneumatic methods in the United States in net tons of clean coal, 1940-43*

Method of cleaning	1940	1941	1942	1943	Change, 1943 from 1942 (percent)
By wet methods:					
At mines.....	78,539,869	91,126,091	111,210,109	114,407,591	+2.9

¹ Based upon shipping weights and includes some marketable coal that did not pass through cleaning plants.

² Includes some coal mined in Pennsylvania and cleaned in Ohio.

³ Includes some coal mined in West Virginia and cleaned in Ohio and Pennsylvania.

⁴ Includes all mechanical cleaning other than washeries operated by consumer steel companies.

⁵ Includes central washeries in Colorado and Pennsylvania operated by consumer steel companies.

DETAILED STATISTICS, BY STATES AND COUNTIES

Detailed production and employment statistics are given in table 41 for each coal-producing county in the United States from which three or more operators submitted reports for 1943. Statistics on counties with less than three reporting producers have been combined with data for other counties in the same State to avoid disclosing individual figures, unless permission to publish has been granted by the operators. Production of mines on the border between two States has been credited to the State from which the coal was extracted rather than to that in which the tippie was situated. If the coal is mined from lands in both States, the tonnage has been apportioned accordingly.

In this series the reported production is classified according to the principal methods of distribution or use. Beginning with 1932, the series was expanded to include data on the growing volume of coal moving from mine to consumer by truck. For 1933-36 this tonnage was shown as "Commercial sales by truck or wagon." In 1937 this tonnage was shown as "Truck deliveries, including local sales" (see Minerals Yearbook, 1939, p. 813). In 1938 the truck tonnage was shown as "Shipped by truck or wagon." The truck figures for 1933 to 1936, inclusive, and 1938 to 1943, inclusive, are reasonably comparable.

The data in the present report, as in those published for many years by the Bureau of Mines, relate only to mines with an annual output

of 1,000 tons or more. That fact should be borne in mind when the statistics in this report are compared with similar data compiled by State mine departments. Differences arise largely from variations in coverage by State reports, some of which include data for all mines regardless of size, and others only data for mines employing more than a specified minimum number, ranging from 2 to 10 men. To meet the administrative demand for statistics on mines with an annual output of less than 1,000 tons per year, data for the small mines are shown in table 42. The average tons per man per day at the small mines was low due to part-time employment, lack of machinery, and difficult working conditions. The production shown in table 42 is not included in the total output shown in other tables for the United States, as this would upset the comparability of the statistical series.

Because of a change in method of reporting, statistics of average production per man per day for 1932 to 1936 and 1938 to 1941 are not precisely comparable with those for other years. For other years they were based upon the calculated number of man-shifts, obtained by multiplying the average number of men employed at each mine by the number of days worked at the mine. From 1932 to 1936 and 1938 to 1941 the operators were asked to make, if possible, a special report of the number of man-shifts actually worked. The number of operators able to furnish this information was small. These reports were utilized to improve the accuracy of the record. Otherwise, the man-shifts were calculated by multiplying the number employed underground and on the surface by the number of days worked by the mine and tippie, respectively.

TABLE 41.—*Production, value, employment, man-days, and output per man per day at bituminous-coal and lignite mines in the United States, by States and counties, in 1943*
 [Exclusive of mines producing less than 1,000 tons]

County	Disposition of coal produced (net tons)				Average value per ton 2	Average number of employees			Average number of days mines were active	Number of man-days worked	Average tons per man per day

Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding for shipment by rail, and bailed by truck to waterway for shipment by water.

Includes coal transported from mine to point of use by conveyor or tram.

Value received or charged for coal, f. o. b. mine, including selling cost. (Includes a value for coal not sold but used by producer, such as mine fuel and coal coked (not coke) as estimated by producer at average prices that might have been received if such coal had been sold commercially.)

No coal was "Made into beehive coke at mine."

Includes 153,762 tons "Made into beehive coke at mine" in Las Animas County.

"Other counties" in Illinois include Bureau, Grundy, Jefferson, Logan, Marion, Warren, Will, and Woodford.

Output obtained chiefly from strip pits and by use of mechanical loading devices, in which types of operations production per man per day is large.

Production of Alston Coal Co. (Alston mine) and Hume-Sinclair Coal Mining Co. (No. 3 and part of No. 1 mine) credited to Missouri; production of Hume-Sinclair Coal Mining Co. (part of No. 1 mine) credited to Kansas.

Output obtained chiefly from strip pits in which production per man per day is large.

Includes 34,024 tons "Made into beehive coke at mine" in Pike County, Ky.

In Montana and South Dakota some lignite "Used at mine for power and heat" included with "Used by employees." In North Dakota some lignite made into briquets included in "Other uses at mine." In South Dakota some lignite "Loaded for shipment" included in "Shipped by truck or wagon."

Includes coal "Made into beehive coke at mine" in the following counties in Pennsylvania: Bedford, 43,100 tons; Cambria, 77,170; Fayette, 4,806,928; Indiana, 320,867; and Westmoreland, 1,629,795—Grand total, 6,879,860 tons.

Includes 6,479 tons "Made into beehive coke at mine" in Grundy County.

In Texas some lignite "Shipped by truck or wagon" and "Used at mine for power and heat" included in "Other uses at mine."

Includes 31,839 tons "Made into beehive coke at mine" in Carbon County.

Output obtained chiefly by use of mechanical loading devices in which type of operation production per man per day is large.

Includes 495,430 tons "Made into beehive coke at mine" in Wise County.

Includes coal "Made into beehive coke at mine" in following counties in West Virginia: Fayette, 327,355 tons; Monongalia, 63,536; Nicholas, 28,840; Preston, 161,368; and Randolph, 2,741—Grand total, 683,840 tons.

SUMMARY OF SMALL MINES

TABLE 42.—Summary of data on mines in the United States producing less than 1,000 tons a year, by States and districts, in 1943¹

[Figures compiled from schedules actually received and supplemented by State mine inspectors' reports where available. Not possible to obtain complete coverage. Data shown in table not included in other parts of this report]

State or district	Number of active mines	Total production (net tons)	Average value per ton	Average number of employees	Average number of days mines were active	Number of man-days worked	Average tons per man per day

¹ Data on small lignite mines in Montana, North Dakota, South Dakota, and Texas not available.

² Includes Alaska, Arizona, and California.

³ For boundaries of districts, see Bituminous Coal Act of 1937 and modifications thereto.

⁴ For purposes of concealment of individual operators' figures, Alaska (district 23) included with district 18.

STATISTICS ON LIGNITE IN 1943⁴

PRODUCTION

Statistics on the lignite industry in the United States were compiled by the Anthracite and Coke Section of the Bureau of Mines from annual reports received from producers of lignite in the areas mapped

⁴ Compiled by J. A. Corgan and M. I. Cooke.

as lignite in Geological Survey Professional Paper 100-A, *The Coal Fields of the United States*. Subbituminous coal, sometimes called black lignite, is not included in these statistics.

The production of lignite in 1943 totaled 2,749,393 tons, exclusive of some small mines that produced less than 1,000 tons. This is a decrease of 6.2 percent from the 2,930,661 tons produced in 1942. The average value per ton was \$1.49 compared with \$1.36 in 1942. Employees totaled 1,165 in 1943 and 1,490 in 1942, the average output per man per day, based upon calculated man-days was 10.98 and 9.84 tons, respectively, for the same periods. The output per man per day is high in the lignite industry compared with other coal mining in the United States because a large part of the total production—70 percent in 1943—is recovered from strip pits where the average output per man per day is much higher than in deep mining.

In 1943, as for many years, North Dakota was the chief producer of lignite, followed in order by Texas, Montana, and South Dakota. The North Dakota output comprised 91 percent of the total, that of Texas 5 percent, and the output of South Dakota and Montana together, 4 percent.

According to the Federal Power Commission, 586,204 tons of lignite were consumed in the West North Central States for generating electric energy in 1943; 20,187 tons, in the West South Central States; and 418,732 tons—a large part of which was subbituminous—in the Mountain States.

The following tables contain detailed statistics for lignite in 1943. Statistics of the lignite industry in 1944 were not available for publication in this chapter but may be obtained in mimeographed form upon request to the Anthracite and Coke Section, Coal Economics Division, Bureau of Mines.

TABLE 43.—*Summary of production, value, men employed, days operated, man-days of labor, and output per man per day at lignite mines in the United States in 1943, by States*

METHODS OF RECOVERY

TABLE 45.—*Lignite mined by different methods in the United States in 1943, by States, in net tons*

State	Mined by hand	Shot off the solid	Cut by machines ¹	From strip pits	Total
Montana, South Dakota, and Texas.....	(²)	78,453	-----	170,738	249,191
North Dakota.....	11,387	128,153	610,940	1,749,722	2,600,202
Total.....	11,387	206,606	610,940	1,920,460	2,749,393

¹ Total of 21 machines used—17 "permissible" and 4 other types.² Small amount of "Mined by hand" included under "Shot off the solid."

NUMBER AND SIZE OF MINES

For 1943 the Bureau of Mines received reports from 131 lignite mines (exclusive of some mines producing less than 1,000 tons a year). Most of the operations were in North Dakota, which had 106; Montana was next in order, with 15 mines; and South Dakota and Texas followed with 7 and 3, respectively. The classification by size of output in the field as a whole in 1943 is given in table 46.

TABLE 46.—*Number and production of lignite mines in the United States in 1943, classified by size of output*

Class	Mines		Production		
	Number	Percent of total	Net tons		Percent of total
			Total	Average per mine	
1. 200,000 tons and over.....	6	4.6	2,000,507	333,418	72.8
2. 100,000 to 200,000 tons.....	1	.8	126,904	126,904	4.6
3. 50,000 to 100,000 tons.....	2	1.6	137,266	68,633	5.0
4. 10,000 to 50,000 tons.....	14	10.7	280,588	20,042	10.2
5. Under 10,000 tons.....	108	82.4	204,128	1,890	7.4
Total.....	131	100.0	2,749,393	20,988	100.0

STRIPPING OPERATIONS

The production of lignite from strip pits in 1943 amounted to 1,920,460 tons—70 percent of the total output of the industry. As for many years, most of the stripping—that is, 91 percent of all strip-pit production and 64 percent of the total tonnage produced by the lignite industry—was done in North Dakota, where 1,749,722 tons were produced by that method. The output from stripping in Texas, Montana, and South Dakota was only 170,738 tons. The number of men employed was 589, with an average output per man per day of 15.99 tons, and the average number of days worked was 221.

Detailed statistics for stripping operations in the lignite industry in 1943 are given in table 47.

TABLE 47.—*Summary of stripping operations that produced lignite in the United States in 1943, by States*

State	Number of strip pits ¹		Coal produced (net tons)		Total value at mines (thousand dollars)	Average value per ton	Number of employees			Average number of days mines operated	Man-days of labor ²	Average tons per man per day ³	
	Number of shovels, drag-line excavators, and coal-loading machines ⁴		Mined by strip-ping	Total at same mines			Underground	Surface					Total
								In strip pits	All others				
Montana and Texas.....	4	4	131,679	131,679	123	\$0.93	—	20	8	28	246	6,898	19.09

REVIEW OF 1944

Although production of Pennsylvania anthracite in 1944 totaled 63,701,363 net tons—a gain of 5 percent over 1943 and the highest output since 1930—demand exceeded production, and allocation was necessary to attain equitable distribution of the supplies available. Shortages of other space-heating fuels in the United States and Canada, expanded purchasing power of domestic consumers, and the high rate of industrial consumption were responsible for the heavy demand for anthracite. Scarcity of manpower and difficulty in obtaining equipment and supplies were the principal factors that limited production in 1944. Although deep-mine production declined slightly from 1943, the production from strip mines and culm banks was the highest on record, and the over-all industry gain of 3,057,743 tons is attributable almost entirely to increased output from these sources. The total of 292 days operated by the industry, including four Sundays worked in February, was exceeded only by the record of 293 days in 1918.

In direct contrast to the unsettled labor conditions that caused an estimated production loss of 5,700,000 tons in 1943, no general stoppages of work occurred in the anthracite industry in 1944. Continuity of operations was threatened, however, because of the absence of a contract. As a result, the Secretary of the Interior continued the control measures established early in 1943 and did not relinquish possession of the mines until June 21, 1944, 4 days after a contract was signed by the operators and miners.

The Anthracite Distribution Program inaugurated in 1943 by Solid Fuels Administration for War was continued through 1944 because of a scarcity of fuels. The Bureau of Mines continued to work closely with the Solid Fuels Administration for War in compiling current detailed statistical data relating to distribution, production, consumption, utilization, and market requirements of anthracite upon which the program for fair distribution of anthracite was based.

The Bureau of Mines, through congressional appropriation, conducted research in the anthracite fields to determine ways to increase the production of anthracite by extending underground mechanization, especially in the pitching seams of the Southern and Western Middle fields, where mechanical mining has made little progress in the past. Investigations were conducted also to determine means of controlling mine water and preventing flooding of the mines. It is expected that the present investigative work will lead to the development of major projects for future consideration.

Research and experimental work conducted by Anthracite Industries, Inc., for many years on the development of new, low-cost, automatic coal-burning equipment has been fruitful, as evidenced by the announcement of the development of an entirely new principle for the utilization of anthracite. The laboratory at Primos, Pa., conducted an expanded program on the development of auxiliary heating equipment and, at the same time, served as a source of technical information for manufacturers of coal-burning equipment.

According to the Anthracite Committee, production of "bootleg" anthracite totaled 1,333,000 net tons during 1944, compared with 1,912,000 tons in 1943, a decrease of 30 percent. Production from this source has declined rapidly since 1941, when the output reached 6,300,000 tons. The chief contributing factor in the decline has been the loss of miners to the armed forces, to nearby war industries, and to established mining companies.

Definition of Pennsylvania anthracite.—The term "Pennsylvania anthracite," so far as this report is concerned, includes all nonbituminous coal mined in Pennsylvania and, for historical purposes, the coal produced in the Bernice Basin in Sullivan County, the latter being officially classified as semianthracite. The anthracite fields are in the northeastern part of the State, and the coal is mined in the following counties: Carbon, Columbia, Dauphin, Lebanon, Lackawanna, Luzerne, Northumberland, Schuylkill, Susquehanna, and Wayne.

Statistical trends.—Tables 1 and 2 present pertinent statistical data on the Pennsylvania anthracite industry.

The war and anthracite.—Despite labor shortages and difficulty in obtaining equipment and supplies, the anthracite industry increased its output 5 percent over 1943, making the tonnage of anthracite available for distribution greater in 1944 than in any year since the start of the war. Even with this substantial increase, however, it was impossible to meet requirements because of the disproportionate increase in demand brought about principally by continued shortages of oil and coke in this country and deficiencies of gas and oil in Canada for space heating. The allocation system established by the Solid Fuels Administration for War in 1943 was continued through 1944. Using statistics compiled by the Bureau of Mines from reports furnished by producers and wholesalers of anthracite, Solid Fuels

Administration for War was able to distribute equitably the available supplies of anthracite. Data for the 1942-43 coal year were used as a base in determining allowable shipments to retail coal merchants and in relieving local shortages, whereas monthly statistics were used to

control supplies between producers and wholesalers. Shipments of domestic and Buckwheat No. 1 sizes to retailers were limited for the first 7 months to 90 percent of adjusted average monthly receipts of those sizes during the 1942-43 coal year and 87.5 percent during the last 5 months when the supply situation became more acute. Regulation of delivery of all sizes was not necessary, as some of the steam coal was in surplus throughout the year. The success attained in distributing anthracite equitably would not have been possible without the cooperation of the producers, wholesalers, and retailers of anthracite.

Anthracite Industries, Inc.—Anthracite Industries, Inc., continued its enlarged scope of research activities, announcing the development of the "Anthratable," a device for utilizing an entirely new method of burning anthracite. The device consists primarily of a horizontal, steel combustion chamber, 18 inches in length and 6 inches in diameter, into which anthracite is pushed by a mechanical worm and where it burns with great intensity under forced draft. A water jacket surrounds the hot part of the tube; and the water, absorbing the heat from the steel, can be circulated through radiators for space heating. It is anticipated that the complete unit will require a space of approximately 2 by 2 by 3 feet and that it will play an important part in competing for the postwar fuel markets. In addition, the laboratory (Primos, Pa.) continued research in the design of other new anthracite-burning equipment and the development of auxiliary equipment to improve the efficiency and convenience of the equipment now in use. Manufacturers of coal-burning equipment and regulatory devices are encouraged by Anthracite Industries, Inc., to cooperate with the laboratory.

Anthracite Committee.—The Anthracite Committee has served the industry not only by representing the producers before various Government agencies in matters affecting their operations but by supplying current statistics on production, employment, and other pertinent phases of the industry, by predicting production trends, and by furnishing information concerning the activities of the "bootleg" mining industry.

Anthracite Institute.—The Anthracite Institute through its expanded information services continued to keep the operators apprised of the many Government regulations regarding the distribution of anthracite, as well as matters relating to freight rates, State and Federal legislation, and many other subjects of interest to the industry. Representatives of the institute cooperated with producers of other solid fuels and members of the transportation industry in opposing the extension of natural gas pipe lines into the eastern markets.

Labor.—There was an acute shortage of labor in the anthracite-mining industry in 1944, especially of men to work at the face; output, no doubt, would have been much greater had sufficient labor been available. In accordance with an agreement between the operators and the miners made early in 1943, the mine workers continued to work 6 days a week throughout 1944. The miners worked 7 days a week in February to increase the output of anthracite, thereby alleviating the shortage of that fuel in its principal markets. The mine workers were paid double time for the extra work, provided they worked the 6 consecutive days before Sunday, and the Office of Price Administration authorized an increase in f. o. b. mine prices

of anthracite to compensate for added costs of production occasioned by the Sunday work. The average number of mine workers employed in 1944 was 77,591, a slight decline from the previous year. On June 17, 1944, after negotiating for about 15 months, the anthracite-mine operators and the United Mine Workers of America signed a new wage contract through April 30, 1945, to supersede the one that expired on April 30, 1943. On two occasions during the period between the expiration of the old agreement and the signing of the new one, the Federal Government took possession of the mines when the miners failed to report for work because of the absence of a contract. On June 21, 1944, the Secretary of the Interior issued Order CMA 39, bringing to a close almost 13 months of continuous Government custody of the mines—from May 1, to October 12, 1943, and from November 1, 1943, to June 21, 1944.

Research.—The Bureau of Mines commenced investigative work in the anthracite fields on increasing the output per man per day of anthracite through new and improved methods of mining anthracite mechanically. Mechanical mining, particularly in the flat areas of the Northern field, has been in effect for many years, but the bulk of the production must eventually come from the pitching seams of the Western Middle, and Southern fields, where mechanization has made slow progress. It is hoped that through extended mechanization mining costs may be reduced, enhancing the economic status of the industry in the postwar period. Concurrently with the mechanization program, investigations were made on control of mine water and flood prevention. Work on flood prevention has been carried on for a number of years by individual companies, but to be effective major problems must be solved on a collective basis. This requires a coordination of jurisdictional bodies and property owners, as well as an established means of financing. Headquarters for the Bureau's activities on these subjects have been established at Wilkes-Barre, Pa.

With a view toward relieving the wartime shortage of certain special metallurgical coals several byproduct-coke plants blended fine-size anthracite with bituminous coal to manufacture coke. Other plants are conducting experiments on blends containing anthracite fines. Reports received by the Bureau indicate that 188,000 net tons of anthracite were used in this manner in 1944. This experimental work has been encouraged by the Solid Fuels Administration for War, not only to alleviate the shortage of low-volatile bituminous coal used in producing coke but also to establish a market for surplus anthracite fines brought about by increased production of the domestic sizes. Details on research and investigations by the Bureau of Mines on the use of anthracite fines at 21 byproduct coke plants were published in Report of Investigations 3808, Utilization of Anthracite Fines in the Manufacture of Byproduct Coke.

The cooperative research program at the Pennsylvania State College, which has been financially supported for 4 years by the Commonwealth of Pennsylvania and the anthracite industry, was extended for a period ending May 31, 1945.

Research conducted by Anthracite Industries, Inc., is discussed in the preceding text of this chapter.

Competitive fuels in the United States and principal markets.—More than 96 percent of the anthracite shipped from the mines to points

in the United States is destined to the New England States, the Middle Atlantic States, Delaware, Maryland, and the District of Columbia. Data on the consumption of all fuels in these markets are not available; however, the apparent consumption of anthracite, coke, briquets, and heating and range oils in terms of anthracite in 1943 declined 3.7 percent from 1942. The decline is attributable entirely to decreased shipments of heating and range oil and coke to these markets. Anthracite shipments increased slightly in 1943 over 1942, supplying 61.7 percent of the total equivalent fuels consumed in these States. In addition to the legitimate anthracite shipped, large quantities of "bootleg" coal are moved by truck to this area. Although complete data for 1944 are not available, it is believed

² An important but undetermined part of anthracite shown as shipped to New Jersey is reshipped New York City.

³ Data not yet available.

⁴ U. S. Department of Commerce.

⁵ Less than 1,000 tons.

⁶ Converted to coal equivalent upon basis of 4 barrels of fuel oil equaling 1 ton of coal.

⁷ Excludes bituminous coal.

that the total consumption of fuels in these markets increased over 1943; slight gains are indicated for coke and anthracite, and it is believed that these gains will offset any small decline in consumption of heating oils. Details on consumption of competitive fuels are shown in table 3.

In general, supplies of fuels commonly used for space-heating purposes in the United States increased in 1944 over 1943, substantial gains being recorded in the consumption of anthracite and coke. Details on supplies of available fuels are given in table 4.

Distribution.—Tables 5 and 6 summarize detailed data, published jointly by the Bureau of Mines and Solid Fuels Administration for

TABLE 4.—Total supplies of fuels commonly used for space-heating purposes in the United States, 1937 and 1941-44

[Wherever available, figures represent quantity actually consumed for domestic heating or for space heating offices, apartments, hotels, schools, hospitals, etc. Where such figures are not available but where the fuel is known to be used chiefly for domestic or space-heating purposes, total production (or imports) is shown to indicate trend of growth]

House heating	45,200	67,151	79,600	83,686	84,766

¹ A considerable part of the smaller steam sizes is used by industries, railroads, and public utilities.

² U. S. Department of Commerce.

³ Production plus imports less exports.

⁴ Partly estimated.

⁵ Data not available.

⁶ An estimated one-half is used for domestic purposes.

⁷ Exact data not available; estimated between 55 and 77 million tons a year, including lignite.

⁸ Estimated.

⁹ Includes all grades of fuel oil used for heating buildings.

¹⁰ Includes gas used for heating offices, hotels, apartments, hospitals, and stores, and other large buildings, as well as houses.

¹¹ American Gas Association.

¹ Distribution data in this table and report are final. Preliminary statistics were published in the chapter Pennsylvania Anthracite, Minerals Yearbook, 1943, p. 954.
² Includes Alabama, Arkansas, Louisiana, Oklahoma, Tennessee, and Texas.
³ Includes California, Idaho, Montana, Nevada, Utah, Washington, and Wyoming.
⁴ Less than 0.005 percent.
⁵ Coal sold to over-the-road truckers for shipment outside the "local sales" area, and for which the destinations were not known.
⁶ Includes Alberta, British Columbia, Manitoba, Prince Edward Island, and Saskatchewan.

⁷ Shipments to final destinations in Canada reported by American and Canadian wholesalers were as listed—4,133,706 net tons. However the total of direct shipment by American wholesalers to final, Canadian destinations and to Canadian wholesalers was 4,396,116 net tons, distributed by sizes as 3,389,505 tons of Domestic, 511,694 tons of Buckwheat No. 1, 351 tons of Rice, and 132,081 tons of all other sizes. The difference is due principally to the incomplete reporting by Canadian wholesalers of shipments to final destinations. Official data from the U. S. Department of Commerce of total exports of anthracite to Canada were 4,429,973 net tons during the coal year 1942-43.

War in Report S. F. D. 1, Distribution of Pennsylvania Anthracite for the Coal Year April 1, 1942, to March 31, 1943. This report, listing shipments to separate destinations, contains the most nearly complete statistics ever released on anthracite distribution. These statistics were furnished by the producers and wholesalers of anthracite to the Bureau of Mines in compliance with Solid Fuels Administration for War Order 1, promulgated July 6, 1943, in initiating a distribution program that became necessary when it was apparent that unless the available supplies of anthracite were distributed equitably, serious local shortages might develop in the winter of 1943-44.

TABLE 6.—*Shipments of Pennsylvania anthracite, April 1, 1942–March 31, 1943, by method of movement, in net tons*

¹ Includes shipments from the mines to destinations outside the "local sales" area.

² Includes shipments to industrials, utilities, railroads, institutions, etc.; this tonnage was transported by all methods of movement and was not separable by type of carrier.

³ This tonnage was transported principally by truck.

As indicated in table 5, Pennsylvania anthracite was shipped to 43 States, the District of Columbia, Dominion of Canada, and other foreign countries. Of the total shipments, 86.3 percent was destined to the New England and Middle Atlantic States and 1.3 percent to "unknown destinations." Inasmuch as 784,270 tons of the total listed under "unknown destinations" were shipped from the mines by truck, it may be assumed that virtually all of this tonnage was

destined to New York, New Jersey, and Pennsylvania. Thus the shipments to the New England and Middle Atlantic States account for approximately 87.6 percent of the total anthracite shipped to destinations in the United States and Canada.

It will be noted in table 6 that, of the total tonnage shipped to retailers, 91 percent (39,956,680 tons) was Buckwheat No. 1 and larger sizes which are used almost entirely for heating homes, apartments, and hospitals and for other space-heating purposes. Of the anthracite shipped to retail dealers, 72 percent moved all-rail, 10 percent by truck, 17 percent by tide, and 1 percent off the Lake docks. The New England and Middle Atlantic States received 83 percent of all the shipments to retail dealers in the United States and Canada. Nearly all of the coal moving by tide was shipped from the New Jersey piers to the greater New York area, while a relatively small tonnage was shipped by water to the New England States.

¹ Department of Mines, Harrisburg, Pa.

Anthracite shipments from the mine to destinations in the United States increased 3 percent in 1944 over 1943, according to data compiled from records of the Pennsylvania Department of Mines. Of the total 1944 shipments, 86 percent moved from the mines by rail and 14 percent by truck, whereas in 1943, 85 percent moved by rail and 15 percent by truck.

Pennsylvania received 78 percent of the truck shipments in 1944; New Jersey and New York followed with 10 percent and 9 percent, respectively. It is interesting to compare these percentages with those of 1941, when Pennsylvania received 66 percent of the total truck shipments, New Jersey 18 percent, and New York 14 percent. This shift in the quantity of anthracite trucked to these States is no doubt a direct result of wartime shortages of gasoline, tires, and other truck equipment. Anthracite rail shipments by States of destination for 1942-44 are shown in table 7, and truck movement in 1944, by months, by States of destination, in table 8.

According to data compiled from the records of the Massachusetts Division on the Necessaries of Life and the Anthracite Emergency Tidewater Bureau, rail receipts of Pennsylvania anthracite in New England increased 10 percent over 1943; tidewater receipts declined 6 percent. Table 9 gives details of anthracite movement to New England. Loadings at Lake Erie ports increased 61 percent and receipts at upper Lake docks 89 percent over 1943. The big increases in the Great Lakes region are due largely to the increased use of the smaller steam sizes of anthracite by briquet manufacturers.

Figure 1 presents graphically shipments of anthracite from the Lehigh, Schuylkill, and Wyoming regions, 1850 to 1944, inclusive.

FIGURE 1.—Anthracite shipped from the Lehigh, Schuylkill, and Wyoming regions, 1850-1944.

Consumption.—Consumption of anthracite in the United States in 1944, including colliery fuel and coal dredged from the streams draining the anthracite fields, totaled 59,400,000 tons, an increase of 4 percent over the calculated consumption in 1943. These data consider exports, imports, and changes in producer stocks of anthracite but do not consider changes in stocks held by retail dealers, as data on stocks held by this group are incomplete. Consumption of anthracite in the manufacture of fuel briquets increased from 388,693 net tons in 1943 to 711,109 tons in 1944; the gain was caused largely by a shortage of low-volatile bituminous coal generally used extensively in making briquets. Consumption of anthracite by electric power utilities increased 5 percent over 1943, whereas consumption by class I railroads declined 9 percent.

Changes in stocks.—Because of the great demand for anthracite for comfort heating in 1944, there were virtually no Domestic and Buckwheat No. 1 sizes in producers' storage during the year. Almost all of the coal in storage at the close of the year was Buckwheat No. 3 and smaller. Stocks held by railroads (class I only) increased 35 percent in 1944 over 1943, whereas stocks held by electric power utilities declined 8 percent, and stocks on the upper Lake docks

increased 105 percent. In January, retail dealers held an 11 days' supply of anthracite; in March, 9 days'; and at the close of the year, 19 days'.

"Bootleg" coal.—The seventh survey of "bootleg" anthracite mining by the Anthracite Committee in March 1945 revealed that 502 "bootleg" holes were being worked by 1,806 men, a substantial drop from the 10,762 men working 3,006 holes, disclosed by the March 1941 survey. A survey by the Committee in May 1942 revealed that 55 percent of the men and boys working in "bootleg" holes were less than 35 years old. A comparable survey in March 1945 indicated that only 37 percent were in this younger group. A large percentage of these younger men had either entered the armed forces or transferred to some war industry. Output of "bootleg" coal totaled 1,333,000 net tons in 1944 compared with 1,912,000 tons in 1943.

In February 1945 a bill was introduced before the Pennsylvania General Assembly giving State mine inspectors authority to enter and inspect any mining operation where two or more men are employed. If passed, this law might bring about virtual cessation of "bootleg" operations, since these mines would have difficulty in meeting the rigid inspection standards of the Pennsylvania State Department of Mines. The present law requires periodic inspection only of those mines employing five or more men. A detailed discussion of "bootleg coal" is contained in a report entitled, "Bootlegging or Illegal Mining of Anthracite Coal in Pennsylvania," Anthracite Coal Industry Commission, Commonwealth of Pennsylvania, Harrisburg, Pa., 1937, 84 pages.

Trend in employment.—The decline in employment from 82,121 men in 1942 to 77,591 in 1944, occurring chiefly among underground miners and their laborers, has been due principally to the induction of men into the armed forces and the loss of others to nearby war industries. These figures do not include men working in "bootleg" holes; for employment in this type of mining, see discussion of "bootleg coal" in this chapter. Data on employment are given in tables 23 and 24.

Sales realization.—To compensate the producers for added production costs incurred in wage agreements with the mine workers, the Office of Price Administration authorized increases in the f. o. b. mine prices of anthracite in November 1943. These increases, together with price advances in February, were reflected in the 1944 prices, thereby increasing the average sales realization on breaker shipments from \$5.38 in 1943 to \$5.91 in 1944. The average value per ton of the total anthracite output was \$5.57, compared with \$5.06 in 1943.

Trend in prices.—The Solid Fuels Administrator for War directed the Federal operating managers of the anthracite mines to give the miners an opportunity to work four Sundays in February to increase the output of anthracite. To compensate the producers for added costs of production due to the Sunday work, the Office of Price Administration authorized an increase of 45 cents a net ton in the f. o. b. mine prices of anthracite for all coal loaded at the preparation plants for shipment during February. The maximum prices before the February increase were: Broken, Egg, Stove, and Chestnut, \$8.00; Pea, \$6.45; Buckwheat No. 1, \$4.80; Rice, \$3.85; and Barley, \$2.85 a net ton, respectively. On March 1 the mine prices reverted to these quotations.

On June 1 the f. o. b. mine prices were decreased an average of 14 cents a ton by order of the Office of Price Administration. That agency stated that the increase of 62 cents a ton, granted the pro-

¹ Compiled from reports of the Bureau of Labor Statistics, U. S. Department of Labor.

Prices are as of 15th of each month. Data are preliminary.

* Insufficient data.

* Includes 2 percent sales tax.

* Includes 1 percent sales tax.

* Prices of coal per ton of 2,240 pounds.

ducers in November 1943 to compensate for increased labor costs allowable under the "Little Steel Formula" and wage agreement of November 3, contained an additional 14 cents to compensate for added labor costs made retroactive to May 1, 1943, by the War Labor Board. Hence on June 1, and at the close of the year the mine prices were as follows: Broken, Egg, Stove, and Chestnut, \$7.85; Pea, \$6.30; Buckwheat No. 1, \$4.65; Rice, \$3.75; and Barley, \$2.75 a ton, respectively.

Retail prices of anthracite, bituminous coal, coke, and heating oils in selected cities, by months, in 1944 are shown in table 10. These prices were compiled from reports of the Bureau of Labor Statistics, United States Department of Labor.

Imports and exports.—Exports of anthracite, 99 percent of which was destined to Canada, increased 1 percent in 1944 over 1943. Imports were negligible totaling only 11,847 tons, a decline of 93 percent from the tonnage imported in 1943. For details on imports and exports see tables 31 and 32.

Mechanical stokers and oil burners.—Government restrictions on the manufacture and sale of stokers and oil burners have been largely responsible for the general decline in shipments of this equipment since 1941. According to the Bureau of the Census, United States Department of Commerce, factory sales of class 1 mechanical stokers for burning anthracite (capacity under 61 pounds of coal per hour) declined from 17,110 units in 1941 to 472 units in 1943 and in 1944 totaled only 450 units. Sales of class 2 stokers (capacity 61 to 100 pounds of anthracite per hour) were 599 units in 1941 and increased to 2,043 units in 1943 and to 2,243 units in 1944. Shipments of oil burners for central heating plants and industrial use totaled 303,869 units in 1941, declined to 72,563 units in 1943, and increased to 77,081 units in 1944.

POSTWAR OUTLOOK

The relative position of the anthracite industry in the highly competitive fuel markets in the Eastern States during the postwar period will depend largely on intensive research and experimental work now and after the war to reduce the cost of mining anthracite and to develop new, low-cost, automatic coal-burning equipment. With the tremendous home-building program that is expected to get under way immediately after the war, the installation of such equipment would play an important part in the retention of customers gained during the war and the addition of new ones. Competition among anthracite, oil, coke, and bituminous coal will be extremely keen in the postwar markets, and to prevent a sharp decline in sales of anthracite it will be necessary for the industry to initiate concentrated marketing and merchandizing programs and for industry associations to cooperate closely with architects, builders, and manufacturers of heating equipment. (See subheadings, Research and Anthracite Industries, Inc.)

SOURCES AND ACKNOWLEDGMENTS

Annual statistics of the Pennsylvania anthracite industry are prepared, for the most part, from reports received direct from the producers and shippers of anthracite, as a result of a canvass con-

ducted by mail. More than 95 percent of the tonnage is reported in this manner, and the remainder is obtained personally by a representative of the Bureau of Mines or from reliable collateral evidence. The information is furnished voluntarily by the producers and is held confidential, as is customary with the statistical services of the Bureau of Mines.

In compiling available information, pertinent statistics prepared by the Pennsylvania Department of Mines, the Anthracite Committee, the Anthracite Institute, and the Association of American Railroads have been used to advantage. The Bureau of Mines gratefully acknowledges the cooperation of these organizations and others from whom information has been received.

PRODUCTION

Production of Pennsylvania anthracite in 1944 totaled 63,701,363 net tons, an increase of 5 percent over the output of 60,643,620 tons in 1943. These statistics include deep-mined and strip-pit production, coal recovered from the culm banks, anthracite purchased by the industry from "bootleggers", and river or creek coal recovered from the streams draining the anthracite fields by dredging. Also included is a small tonnage of semianthracite (147,217 tons in 1944) produced in Sullivan County. In addition to the production of 63,701,363 net tons, the industry shipped 507,590 tons of slush, that is, the settlings from the water used in cleaning anthracite. The marketing of this material, a necessity occasioned by the shortage of coal during the winter of 1944-45, probably will be discontinued in the postwar period. As the coal was generally unprepared, the average value received for it was only about 30 cents per ton compared with \$1.67 a ton for the Buckwheat No. 4 size. This material was excluded from the production statistics to avoid distortion of values, shipments, and output per man per day and to keep the data comparable with those of previous years. See tables 13 to 19 for production and shipments by regions, fields, and counties.

Before 1930 anthracite was produced only by companies who owned or leased the coal lands. During the depression in the early 1930's, unemployed miners commenced to mine anthracite in the Lehigh and Schuylkill regions from lands of the operating companies without permission of the owners, transporting the coal to market by truck. Before 1941 this coal, generally referred to as "bootleg coal," was not included in the production statistics of the Pennsylvania anthracite industry by the Bureau of Mines. In 1941, however, the anthracite industry started to purchase run-of-mine coal from the so-called "bootleggers" for preparation and shipment to market. In 1943 these purchases totaled 1,265,617 net tons; in 1944, 506,842 tons. Since it has been ruled impractical to segregate this purchased anthracite from the output of the industry proper, it is included in the various production tables in the Minerals Yearbook chapters on Pennsylvania anthracite for 1941-44. As a result, the production statistics for the last 5 years are not exactly comparable with those of previous years. To compute the output per man per day for the anthracite industry, it was necessary to deduct the "bootleg" purchases from the total tonnage shipped by the legitimate industry because adequate data on man-days required to produce this tonnage are not available.

Details on this procedure are discussed under Labor Statistics. "Bootleg" coal is discussed under the subheading "Bootleg" Coal.

Weeks and months.—Tables 11 and 12 summarize statistics of weekly and monthly production of anthracite. Data of current output are estimated from records of carloadings and from tonnage reports from trade sources. The weekly and monthly figures have been adjusted to the annual total ascertained by direct canvass of the operators.

Small mines and intercompany sales.—In recent years conditions have favored the development of numerous small mines operating on lease or subcontract and producing run-of-mine coal, which is sold to larger companies for preparation at a breaker. (This refers to legitimate mines only and does not concern illicit or "bootleg" mines.)

¹ Production is estimated from weekly carloadings as reported by the Association of American Railroads and includes mine fuel, coal sold locally, and dredge coal.

² Includes some "bootleg" coal purchased by legitimate operators and prepared at their breakers.

At the same time, an increasing transfer of coal from one operation to another has developed, and some of the companies have built central breakers to which coal from numerous mines is shipped by rail or truck for preparation. These developments have increased the complexity of the task of collecting and compiling statistics of the industry. Great care has been exercised, however, to avoid double counting of tonnages produced by one operator and prepared for market by another, and the figures herein represent the net quantity of merchantable coal plus the fuel used by the collieries themselves. The employees of operators producing run-of-mine coal only have been included in the employment statistics, as they have received wages from the industry and have contributed to the final product.

Regions, fields, and counties.—The anthracite fields are divided into three trade regions—Lehigh, Schuylkill, and Wyoming. This classification is generally used by the trade, and it is also followed in the district organization of the United Mine Workers of America, in which district 1 corresponds to the Wyoming region, district 7 to the Lehigh region, and district 9 to the Schuylkill region. Geologically the anthracite area is classified by fields—the Northern, Eastern Middle,

1 Small quantity of washery coal included with breaker.

PENNSYLVANIA ANTHRAX

Western Middle, and Southern. This classification is based on operating studies because it follows more closely the geological conditions that largely influence the methods and costs of production. The Northern field is the same as the Western Middle field and that part of the Southern field known as the Panther Creek Valley. The Southern field, including the Schuykill region comprises that part of the Western Middle west of Tamaqua and the Western Middle east of Tamaqua. In comparison, the tonnage of the small Berks field is about equal to the statistics of the Northern field. The Schuylkill field is classified officially as semianthracite. The total area of the Schuylkill field is 484 square miles—the Northern covers 242, the Southern 242. Middle 33, the Western Middle 94, and the Southern 146. Based upon minable reserves, the Southern field is the largest, followed by the Western Middle, Northern, and Eastern. The Eastern field is the smallest. Tables 13 to 19 present production statistics for the various counties.

TABLE 14.—*Penyslvania anthracite shirvel fuel in 1944*

[illegible]

in net tons

	Total
000	764,000
000	1,076,000
4,000	2,648,000
08,000	5,028,000
700,000	6,128,000

Culm-bank coal.—The record production from culm banks in 1944 comprised 15 percent of the total anthracite output. In the early days of anthracite mining the smaller sizes of anthracite, especially Pea and under, were not used as they are today, and these sizes and larger pieces of refuse containing much good coal were piled in banks throughout the region. With the current heavy demand for anthracite, the recoverable coal in the culm banks is being rapidly depleted, and it is doubtful whether the production attained in 1944 from this source can be maintained for more than a few years. Tables 17 and 19 give details on culm-bank output.

Interregional variation in sizes.—Because of geological conditions and mining methods used, the percentage yield of domestic sizes of anthracite is greater in the Wyoming region than in either the Lehigh or Schuylkill. The breaker output of domestic sizes declined from 65.9 percent in 1940 to 62.8 percent in 1944, whereas the steam sizes increased from 34.1 to 37.2 percent. The decline in the percentage of domestic sizes and the gain in the steam sizes during this period are due principally to large proportionate gains in the output of culm-bank coal, which yields a large percentage of steam sizes. Table 20 shows, by regions, the percentage of sizes in relation to total breaker output.

¹ Quantity of Lump included is insignificant.

AVERAGE VALUE AND SALES REALIZATION

The average realization figures in this study represent value at the breaker, washery, or dredge reported by the operating companies. The company is requested to "estimate value of the product not sold" and to "exclude selling expenses" in making its report. From this it will be seen that when a producing concern sells its output to a separately organized sales company the value reported will exclude the margin of the sales company and may therefore be somewhat less than the circular price at which the coal is placed on the general market. This fact should be borne in mind in considering the variations in value among different regions, for the same sizes of coal, as shown in the tables.

The average sales realization per net ton on breaker shipments was \$5.91 in 1944, compared with \$5.38 in 1943—a 9.9-percent increase. (See table 21.)

With the inclusion of local sales, colliery fuel, washery coal, and dredge coal the average value per net ton of the total 1944 production is \$5.57, compared with \$5.06 in 1943. (See table 22.)

¹ Value given for shipments is value at which coal left possession of producing company and does not include margins of separately incorporated sales companies.

LABOR STATISTICS

The number of men employed in the Pennsylvania anthracite industry continued to decline in 1944, totaling 77,591 men, compared with 79,153 in 1943. This figure was several thousand below the number necessary to produce enough anthracite to meet requirements. The decline may be attributed largely to induction of men into the armed forces and to others obtaining employment in nearby war industries.

The employment statistics in this chapter do not include workers in "bootleg" coal mining conducted in the Southern and Western Middle fields of the Pennsylvania anthracite regions. According to the Anthracite Committee, 10,762 men were working in this industry in March 1941, and in March 1945 a comparable survey revealed 1,806 men employed. Although these workers are not included in the employment data, the coal produced by some of them was purchased by the legitimate industry for preparation and shipment to market, and coal so purchased is included in the production tables of this chapter. Complete employment data for the "bootleg" holes from which this coal was produced are not available. In calculating the output per man per day, therefore, the tons of "bootleg" coal purchased by the industry proper were deducted from the total tonnage reported by the operators, and the resulting production was then used to calculate the output per man per day. It is true that part of the time of the men employed at the preparation plants of the large companies was used to prepare this purchased coal for market; however, on a per-ton basis this time is insignificant, and its omission will not detract materially from the validity of the result obtained.

See tables 23 and 24 for details on labor statistics.

EQUIPMENT AND METHODS OF MINING

Mechanical loading.—The tonnage of anthracite loaded mechanically in 1944 increased slightly over 1943, accounting for 36 percent of the total underground production. This tonnage no doubt will be higher in 1945 when wartime restrictions on the purchasing of equipment have been eased. Five times as much coal was loaded mechanically in the Wyoming region, where the coal measures are more adaptable to current mechanical loading methods, than in the other two regions combined. Details on mechanical loading are given in tables 25 to 27. Figure 2 illustrates the relative growth of underground mechanical and hand loading and stripping, 1928-44.

FIGURE 2.—Relative growth of mechanical loading, hand loading, and stripping of Pennsylvania anthracite, 1928-44.

Strip-pit operations.—The record production from strip pits in 1944 comprised 21 percent of the total fresh-mined output, compared with 17 percent in 1943 and 4 percent in 1930. As the output per man per day from strip pits is much higher than that in underground mines, production from this source alleviated considerably the shortage of anthracite occasioned by the scarcity of manpower. The Lehigh and Schuylkill regions are the scenes of the largest strip-pit operations in the anthracite fields, having supplied 85 percent of the total 1944 strip-pit output; the Wyoming region supplied the remaining 15 percent. The high proportionate tonnage obtained by stripping in the Lehigh and Schuylkill regions is due largely to the relative ease of mining thick-bed outcrops. In the Wyoming region the beds are thinner, thus limiting the quantity of coal recoverable by strip mining. Draglines are used extensively in removing overburden and at

some pits in loading coal. The largest dragline in the producing area, a walking-type machine with a bucket capacity of 25 cubic yards and a 180-foot boom, was placed in operation during the latter part of 1944. Details of strip-pit operations are given in table 28. Figure 3 illustrates graphically the production of anthracite from strip pits, by regions, 1928-44.

FIGURE 3.—Pennsylvania anthracite mined from strip pits, by regions, 1928-44.

Cutting machines.—The quantity of anthracite cut by machines in 1944 decreased 18 percent compared with 1943; details are shown in table 29.

Dredge coal.—The streams draining the anthracite regions have been a source of coal since about 1890. During the war period this coal has played an important part in alleviating shortages of industrial coal in the market adjacent to the anthracite regions. The dredging industry reached a peak in 1941, when 1,518,000 net tons of anthracite were taken from the river and creek beds; in 1944 dredge output totaled 1,373,000 tons, virtually all of which was Buckwheat No. 3 and smaller sizes. (See table 30.)

FOREIGN TRADE ¹

Anthracite exported from the United States in 1944 totaled 4,185,933 net tons compared with 4,138,680 tons in 1943. Virtually all of the exported coal was shipped to Canada, where shortages of heating gas and coke created a strong demand for anthracite. Details of imports and exports are shown in tables 31 and 32.

Canadian market.—Coal and lignite production in Canada in 1944 decreased 4.8 percent from 1943, whereas coke production increased 12.8 percent. Imports of anthracite decreased 1.0 percent from 1943, but imports of bituminous and subbituminous coal increased 0.5 percent. Coal available for consumption in 1944 was 1.5 percent less than in 1943, whereas coke available for consumption increased 7.4 percent.

See table 33 for coal and coke statistics in Canada.

SUMMARY

In 1944 the coke industry, with increased byproduct-coking capacity, surpassed all earlier production records, supplying coke and byproducts vitally needed for war and many other essential industries. This outstanding production record not only enabled the blast furnaces to maintain an operating ratio of 91.7 percent of capacity but also increased by a million and a half tons the quantity of coke available for the domestic market. The efficient coordination of labor and management reflected in the continuity of operations in the byproduct segment of the industry was an important factor in accomplishing this record.

The combined production of byproduct and beehive coke totaled 74,037,817 tons in 1944, an increase of 3 percent over 1943. The ultimate increase of 3 percent represented in the record output was registered from a 5-percent increase in the production of byproduct coke and a proportionate decrease of 12 percent in the output of beehive coke, resulting generally from the expansion of byproduct coke-making facilities. A shortage of labor and coking coal at the beehive ovens contributed also to the decline of coke from this source.

An important factor in achieving the record production of byproduct coke in 1944 was the byproduct-coal diversion and stock-pile program initiated in 1943 and continued through 1944 by the Solid Fuels Administration for War. Some of the operators were unable to contract for enough coal to keep their plants running at capacity, and to alleviate this situation the above agency issued specific directives

FIGURE 1.—Average daily production of beehive and byproduct coke and pig iron and producers' stocks of byproduct coke, 1935-44, by months.

during the summer and fall requiring coal producers to ship additional tonnages to these plants. Coal was also diverted from by-product-coke plants with large stock piles as well as industrial plants using byproduct coal for generating steam. The Bureau of Mines continued to work closely with the Solid Fuels Administration for War in collecting and compiling current statistical data relating to requirements, consumption, stocks, and days' supply of coking coal at byproduct-coke plants.

Requirements of coke paralleled the output, and calculated consumption for all uses in the United States totaled 72,971,401 tons, an increase of 2 percent over 1943. As in previous years, about 80 percent of the coke consumed was used as metallurgical fuel in blast furnaces. Coke used for other purposes (in foundries, for manufacturing water gas, and other industrial uses) declined slightly, whereas the consumption of domestic coke increased 37 percent over 1943.

The average cost of coal per net ton delivered at byproduct and beehive ovens increased 8 percent over 1943 and reached an all-time high of \$4.90. The average cost per ton of \$5.08 for byproduct coal was 38 percent higher than the immediate prewar maximum of 1940 and approached the peak cost of \$5.40 per ton in 1920. In the beehive industry, coal costs exceeding all previous figures were \$0.16 per ton higher than the previous all-time high of \$3.14 in 1920. These increases in 1944 were due largely to the general increase in mining costs occasioned by higher labor costs under the wage agreement of November 3, 1943, between the coal producers and the miners. As coke prices are determined largely by coal and labor costs, the average realization per ton on coke sales advanced \$0.71 over 1943.

As in previous years, foreign trade in coke was insignificant; in fact, exports amounted to but 1 percent of the total coke output, and imports, all from Canada, constituted only 0.09 percent of the calculated consumption of the country.

Accompanying the increased activity of the byproduct-coke industry in 1944, production of the four principal byproducts soared to new levels. The output of crude tar increased 4 percent, ammonium sulfate or equivalent 5 percent, crude light oil 7 percent, and gas 5 percent. The value realized through the sales of all byproducts (excluding the value of tar used by producers and breeze produced) increased 2 percent over 1943. The importance of the coke byproducts to the war industries is illustrated by the number of allocation orders issued by the War Production Board in prior years and continued through 1944. The value of all coke, breeze, and byproducts in 1944 exceeded 700 million dollars and for the fourth consecutive year established a new peak.

The survey of employment and accidents in coke-oven plants in 1944 by the Bureau of Mines revealed that, in the byproduct-coke industry, 21,586 men were employed and worked a total of 62,848,032 man-hours, compared with 21,632 men working 62,652,039 man-hours during 1943 in the beehive industry, according to preliminary estimates, 3,100 men were employed for a total of 6,400,000 man-hours, compared with 4,133 men working 8,026,872 man-hours in 1943.

GOVERNMENT CONTROL MEASURES

With the coke industry heavily engaged in war production during 1944, various regulations established by Government war agencies in

previous years for the conservation, efficient utilization, and price stabilization of the products related directly to the coke industry were continued in general. However, in order to coordinate the control of coking coal, coke, and byproducts in all their forms and applications it became necessary to revise and modify the terms of some of the measures previously established and in some cases to promulgate new regulations. The outstanding actions taken by the war agencies in 1944 with respect to the coke industry are summarized below.

War Production Board.—On April 28, 1944, the War Production Board delegated to the Solid Fuels Administration for War power to control the distribution of coke from all sources whenever intended for ultimate domestic use. Authority had been previously delegated to control the distribution of coke for domestic use from retail dealers' yards only. Because of the close relationship between the production of coke and steel, movement of coke for industrial use remained under the jurisdiction of the War Production Board.

Effective July 1, 1944, toluol, benzol, and xylol became subject to the provisions of General Allocation Order M-300, which governed the use and delivery of these chemicals; byproduct ammonia and sulfate of ammonia were made subject to this order December 26, 1944. Previous allocation orders regulating these products were revoked.

Office of Price Administration.—Maximum price regulations¹ for byproduct and beehive coke in effect at the end of 1943 were continued in 1944. Amendment 2 to Maximum Price Regulation 29, issued on January 21, increased the price of byproduct coke produced in the East \$0.50 per ton to compensate for added costs of coal resulting from the wage agreement of November 3, 1943. Amendment 2 to M. P. R. 77 increased the price of beehive coke, except for furnace coke made in Connellsville district of Pennsylvania, \$1 per net ton for machine-drawn coke and \$1.25 for hand-drawn coke. This amendment was issued January 4, 1944, and prices were made retroactive to November 23, 1943. Prices of beehive coke produced in Wise County, Va., were increased \$0.75 per ton by amendment 3 of January 18, retroactive to November 29, 1943. Prices of \$9.10 and \$6.50 per net ton, f. o. b. ovens, respectively, were established on February 11 (amendment 4) for beehive foundry and domestic coke produced in Fayette County, W. Va., an increase of approximately \$1 per ton over the maximum prices previously applicable to sales of such coke.

On January 11, 1944, M. P. R. 447, covering crude coal tar, was amended to eliminate the inapplicability of price regulations to transactions under participating and barter-type contracts.

Solid Fuels Administration for War.—On March 2, 1944, the Solid Fuels Administration for War issued Regulation 16 to provide for orderly shipment of byproduct coal, and coke producers were required to furnish information on the tonnages contracted for shipment during the coal year 1944-45, by sizes and sources, as well as information concerning estimated tonnages not contracted for, but required to meet minimum needs. A preference system established early in 1943 for distribution of bituminous coal mined in certain producing districts was continued under provisions of Regulation 20, issued March 30, 1944, which required that producers and whole-

¹ Bureau of Mines, *Minerals Yearbook*, 1943, p. 985.

salers (including dock operators) arrange their distribution schedules so that first preference be given to byproduct and other special-purpose coal commitments and second preference to Lake-coal commitments.

Regulation 23, issued July 17, 1944, included the preference provisions of Regulation 20; and, in addition, this regulation required that shippers in producing Districts 7 and 8, after arranging to fill orders of industrial consumers for byproduct and special-purpose coal and for Lake coal, fill orders of retail dealers whom they supplied during the 1943-44 coal year to the extent of 90 percent of their last year's shipments. The stock piling of bituminous coal by byproduct and special-purpose consumers was regulated under terms specified in revised Regulation 10, issued April 20, 1944.

Early in 1944, the S. F. A. W. placed limitations on deliveries of coke by retail dealers similar to those already in effect on anthracite and on June 20, 1944, Order 17 was issued requiring the filing by producers and wholesalers of information showing the State destinations of coke shipments for domestic use, by months, for the calendar year 1944. S. F. A. W. Order 16, issued on the same date, required the filing of data on export shipments, by sizes and uses.

TECHNOLOGIC DEVELOPMENTS

The expanded wartime requirements for coking coal, metallurgical coke, and coke byproducts have led to a corresponding growth in the demand for technical information. Seeking additional sources of fuel for the blast furnaces of the West's war-born steel industry, a Bureau of Mines diamond-drilling program proved a reserve of 15,345,000 tons of coking coal in the Kemmerer district of Lincoln County, Wyo., of which an estimated 11,215,000 tons are considered recoverable.²

Continuing its program relating to scientific studies on the carbonizing properties of American coals, the Bureau of Mines published a paper³ which discusses the development of test methods and outlines the uses to which the methods have been put in promoting the war effort. In addition, the paper brings the index of coals tested by the BM-AGA method up to date.

Several studies on the problem of economic utilization of anthracite fines as a substitute for low-volatile bituminous coal in admixtures for use in the manufacture of byproduct coke were made.⁴ Conclusions reached by these studies indicate that, in general, anthracite fines can be used in coking-coal mixtures. However, the effect of their addition varies considerably with the nature of the bituminous coals used and the operating conditions at the plant.

One of the problems encountered in the program of the Coke Production Committee and the Bureau of Mines to improve the quality of byproduct coke has been the prevalent lack of control of bulk density of the coal in the coke ovens. It is generally agreed that the chief causes

of variation are probably the fluctuations in the moisture content of the incoming coal, the variations in the screen analysis of the crushed coal, and, to a lesser extent, the variations in the specific gravity of the coal particle size and its distribution, particle shape, and condition of surface. Tests were made on samples of coke-oven charges from several operating plants that were experiencing difficulties because of lack of adequate control of bulk density. Results of these tests are summarized in a report recently prepared by Landers and his associates.⁶ Some coke producers have studied the problem of finding a low-volatile coal substitute for mixing with high-volatile coal for charging high-temperature coke ovens. An account is given of the experimental work and the results obtained by the Colorado Fuel & Iron Corp. in producing and using low-temperature "char" for this purpose. "Char" is produced by partial devolatilization at a low temperature of high-volatile coal, and it is claimed that the blending of this "char" definitely has improved the quality of the coke made from Colorado coal.⁶

A process is claimed for obtaining crystalline naphthalene directly from a side stream rich in naphthalene from a tar-distillation plant. This requires maintaining the side-stream liquid at a temperature just above the crystallization temperature of naphthalene, followed by shock cooling and immediate draining and centrifuging of the crystals.⁷

POSTWAR OUTLOOK

The postwar outlook for the coal-carbonization industry seems quite favorable; and, although the present rate of producing over 74 million tons of coke per year will not be maintained, operations should be well above those of the immediate prewar years.

Past experience proves that coke production is predicated mainly on the demand for metallurgical fuel. Representatives of Government and industry have estimated that near-future demands for pig iron will vary from 40 to 50 million tons annually. Proportionately, blast-furnace and foundry-coke requirements should range from 39 to 48 million tons per year. Of the production of byproduct and beehive coke in the period 1935-39, deliveries to iron blast furnaces and foundries accounted for 70 percent; domestic consumers used 20 percent; and the remaining 10 percent was used for miscellaneous industrial purposes. In view of the relative facilities for the production and distribution of coke and byproducts, it seems reasonable to assume that the immediate postwar period will find these products consumed in much the same ratio as in the immediate prewar years. Therefore, applying 70 percent to 39 million tons—the lower of the two figures representing blast-furnace and foundry-coke requirements—total coke production in the postwar period should approximate 56,000,000 tons. As in the past, the domestic market should absorb between 8½ and 11 million tons and industrial purposes the balance. This production will be obtained primarily from byproduct ovens, as recent developments in the beehive industry indicate that production

from this source will decline rapidly as soon as the wartime peak demand for steel has subsided, and it will again resume the status of a standby industry.

Smoke pollution of the atmosphere is being given more attention, and many cities now have smoke-abatement ordinances. Smokeless fuels can be obtained by carbonizing coal, which is preeminently a method of using coal to a better advantage than burning it in the raw state. Recent developments in the production of synthetic rubber, plastics, insecticides, and other chemicals obtained from raw materials originating in coal carbonization will provide markets for increased quantities of the byproducts. These developments, plus potential projects now in the laboratory stage, should provide excellent and continuing opportunities for the carbonization industry in the near future. Of course, should the cost of coal advance beyond certain economic limits, it will have a retarding influence on the development of the byproduct industry in the postwar period.

TABLE 1.—*Salient statistics of the byproduct and beehive coke industry in the United States in 1944*

	Byproduct	Beehive	Total
Coke produced—			
At merchant plants:

Total byproducts, including breeze ¹	\$2.974	\$2.982	\$3.100	\$3.123	\$3.102

¹ Figures revised to exclude value of crude tar used by producers for refining. Before 1944, value of tar used by producers included the value of that refined or "topped" and accordingly pyramided slightly the credit value of crude tar and its products.

SCOPE OF REPORT

This report presents final statistics for the year 1944 on the byproduct- and beehive-coke industry of the United States, together with salient statistics concerning the related industries of low- and medium-temperature carbonization and coal-gas works. In accordance with usual procedure, most of the tables herein include comparable data for 3 or 4 preceding years. Statistics on medium- and low-temperature carbonization operations have been included with those of the byproduct industry in previous years but are shown separately in 1944, because three such companies reported and hence individual figures will not be revealed. Since only coke made by high-temperature carbonization of coal in byproduct and beehive ovens is suitable for metallurgical purposes, statistics of this report are confined thereto unless otherwise specified. Coke is also made by other processes not included in this report, among which are the refining of petroleum and of crude coal tar. The production of petroleum coke in the United States in 1944 reached 1,803,400 tons; output of coal-tar-pitch coke varied only slightly from the preceding year and totaled 82,800 tons.

Because of the extremely low ash content of petroleum and pitch coke, it is in demand as a source of comparatively pure carbon and is used widely in the manufacture of carbon electrodes.

The standard unit of measurement in the coke industry is the short, or net, ton of 2,000 pounds and, unless otherwise specified, is employed throughout this chapter.

COKE AND COKE BREEZE

MONTHLY AND WEEKLY PRODUCTION

TABLE 3.—*Byproduct, beehive, and total coke produced in the United States, 1937 and 1942-44, by months and average per day, in net tons*¹

Month	1937		1942		1943		1944

¹ Before 1941 daily average production of beehive coke was calculated by subtracting Sundays and holidays in each month; 1942-44 daily average has been calculated by dividing total monthly production by total number of days in month.

PRODUCTION BY FURNACE AND NONFURNACE PLANTS

Definitions used by the Bureau of Mines classifying byproduct-coke plants according to "furnace" and "nonfurnace" groups have been given in previous Coke and Byproducts chapters and therefore need not be repeated here. This classification is maintained by the Bureau in order that trends of activity for these two groups of plants may be followed.

"Furnace" plants, because of their close relationship to the iron and steel industry, normally follow the activity of this industry. Therefore, the output of coke from this group tends to fluctuate more than that of "nonfurnace" plants, depending on the demand for metallurgical fuel. For example, furnace plants in 1944 accounted for 78.9 percent of the total byproduct-coke production, compared with 53.8 percent for the depression year of 1932. Because of the large demand for coke during 1944, the average daily production rate for both groups remained relatively constant.

The recent expansion in blast-furnace capacity has increased greatly the requirements for metallurgical fuel, and production of coke from furnace plants has increased 46 percent since 1937, accompanied by a gain of 10 active plants. In the nonfurnace group, output in the same period increased 8 percent, although 6 fewer plants were active in 1944 than in 1937. The loss in production from these 6 plants (4 plants classified as nonfurnace in 1943 are now classified as medium- and low-temperature carbonization plants) was offset by new coke-oven construction at a number of nonfurnace plants active at the end of 1944.

TABLE 7.—Number and production of byproduct-coke plants connected with iron furnaces and of other plants in the United States, 1913, 1918, 1937, and 1943-44

Year	Number of active plants		Coke produced (net tons)		Percent of production	
	Furnace plants	Other plants	Furnace plants	Other plants	Furnace plants	Other plants
1913.....	20	16	9,277,832	3,436,868	73.0	27.0
1918.....	36	24	19,220,342	6,777,238	73.9	26.1
1937.....	43	42	36,134,209	13,076,539	73.4	26.6
1943.....	50	41	48,992,643	14,750,033	76.9	23.1
1944.....	53	35	62,919,844	14,144,951	78.9	21.1

TABLE 8.—Monthly and average daily production of byproduct coke by plants connected with iron furnaces and by all other plants in the United States, 1937 and 1943-44, in net tons

PRODUCTION BY STATES AND DISTRICTS

Reports received from 88 active byproduct-coke plants operating in 22 States in 1944 revealed that production increased in all but 4 States when compared with 1943. As in previous years, Pennsylvania led all producing States and contributed 25 percent of the byproduct total. This State, with Ohio, Indiana, New York, and Alabama, supplied 72 percent of the total for the country—approximately the same proportion as in 1943. The largest gains in tonnage over 1943 were attained in New York and Indiana, with increases of more than 700,000 tons each. Completion of the new byproduct plant by the Geneva Steel Co. in Utah increased production in that State by 207 percent over 1943. Texas became an active producer of byproduct coke in 1944 for the first time as the Lone Star Steel Co. and Sheffield

Steel of Texas started new ovens in the early part of the year. However, the Lone Star Steel Co. ceased operations on July 4, 1944, leaving only 1 plant active in Texas at the close of the year. Of the gain of 17.9 million tons in byproduct-coke output since 1937, Ohio, Indiana, and Pennsylvania together accounted for more than 57 percent of the total increase.

The decline in beehive blast-furnace coke requirements in 1944 resulted in a decrease in output in all but one of the beehive-producing States. As the preponderance of beehive coke comes from the famous Connellsville coal field of Pennsylvania, this State had the largest decrease in tonnage, with a drop of more than 750,000 tons from 1943 and 1.1 million tons from 1942—the peak year in beehive production in Pennsylvania since 1926. Marked decreases were also recorded in Utah, Virginia, West Virginia, and Tennessee, with the largest decrease in terms of percentage in Tennessee, where production dropped 82 percent.

¹ Includes plants at Bethlehem, Chester, Philadelphia, Steelton, and Swedeland.² Includes plants at Aliquippa, Clairton, Erie, Johnstown, Midland, Monessen, Neville Island, and Pittsburgh.³ Comprises figures from 1 plant each in Beaver, Cambria, and Greene Counties and 2 plants in Indiana County.

NUMBER AND TYPE OF OVENS

Byproduct ovens.—The tremendous wartime construction program in the byproduct-coke industry was virtually completed in 1944, when the number of new ovens contracted for and placed in operation since 1939 totaled 1,973 with a maximum annual coke capacity of 10,651,300 tons. An analysis of the new ovens built since 1939 shows that 1,638 new ovens with a yearly coke capacity of 8,924,000 tons have been built for companies directly engaged in the production of iron and steel. The remainder have been built for merchant plants or for gas companies, from which coke and gas is manufactured for industrial and domestic use. In addition to new ovens, 14 batteries consisting of 758 ovens have been completely rebuilt since 1939, raising the number of new and rebuilt ovens to 2,731. Of the 14,580 byproduct ovens reported in existence at the end of 1944, 40 percent were Koppers-Becker, 36 percent Koppers, 14 percent Semet-Solvay, 9 percent Wilputte, and the remaining 1 percent other miscellaneous types.

Beehive ovens.—Beehive-coke ovens have furnished an important part of the Nation's blast-furnace coke requirements during World War II. At the beginning of our defense program, when steel demand was surging and coke requirements for blast-furnace use were hitting new highs, beehive ovens—long-abandoned—were hurriedly rebuilt and placed in operation to supplement byproduct-plant deficiencies. Thus, in April 1939, an average of 990 beehive ovens was in active operation; the number increased steadily until a peak of 13,819 was reached in September 1943. However, the cut-back in pig-iron production in 1944, coupled with increased byproduct-coke output, reduced the requirements for beehive blast-furnace coke, and a number of ovens were shut down and some were again abandoned. The average number of active beehive ovens in December 1944 amounted to 9,084 (32 percent) less than in the peak month of January 1944.

CAPACITY OF BYPRODUCT PLANTS

Tables 15 and 16 show the potential maximum annual coke capacity of all ovens in existence, whether idle or active, and the relationship between capacity and production for 1937 and 1941-44. The basis upon which potential maximum capacity of a coke plant is established is the minimum coking time at which the ovens can be operated to produce coke with qualities suitable for the use for which it is intended. This may differ from the rated capacity of a coke-oven plant, which is the number of tons of coke per year that the plant is designed to produce. Potential maximum annual coke capacity, as thus stated, is subject to change from year to year, depending on the age and condition of ovens, character and quality of coal charged, and economic and labor conditions.

The potential maximum daily capacity of the 89 byproduct-coke plants in existence December 31, 1944, both idle and active, was 197,623 tons. The daily capacity of furnace plants was 155,698 tons; operation was at 89.4 percent of capacity. That of merchant plants was 41,925 tons; operation was at 90.8 percent of capacity. The operating ratio for the year was slightly lower than for either 1942 or 1943 because many of the older batteries at various steel plants that have been operating at top speed during the war period required longer coking periods to avoid serious damage to old brickwork in the oven walls. As will be noted in table 16, the rate of production may fluctuate widely with variations in the activity of the heavy industries.

TABLE 15.—Potential maximum annual coke capacity of all byproduct coke ovens in existence in the United States, 1937 and 1941-44

Year	Number of plants	Number of ovens	Potential maximum annual coke capacity (net tons)	Percent of change from 1937

¹ Capacity of all ovens in existence, whether active or idle, based upon maximum daily capacity times days in month.

QUANTITY AND COST OF COAL CHARGED

Wartime expansion in coal-carbonizing capacity has increased greatly the requirements for coking coal, and in 1944 more than one-sixth of the total output of bituminous coal was consumed in byproduct- and beehive-coke ovens. The quantity charged into byproduct ovens increased 5 percent over the previous record figure in 1943 and reached a new high of 94,437,887 tons. The quantity carbonized in byproduct ovens, by months, in 1944 was rather uniform and illustrated the continuity of operations. The diminished requirements for beehive coke in 1944 resulted in a decrease of 13 percent in beehive coal consumption, and the quantity consumed each month dropped steadily, so that in December the quantity used was 41 percent lower than in January.

Table 18 shows the quantity of coal charged into ovens in each State and the value at the oven. The cost of coal constitutes the chief expense in the manufacture of coke, and it may vary widely, depending chiefly on the location of the coke plant, with relation to its sources of coal—in other words, in cost of transportation. In 1944, the total value of coal f. o. b. ovens increased 11 percent over 1943 and ranged from \$2.91 in Virginia where beehive coke is made at the mines, to \$6.35 in Minnesota where the cost includes transportation charges from distant mines.

Table 20 shows the cost of coal and value of all products per ton of coke produced. In 1944, the value of beehive coke per ton as reported by operators was \$7.04, whereas the cost of coal charged into ovens per ton of coke drawn was \$5.15. It is not to be assumed that the margin of \$1.89 between these two figures represents the profit realized by the operator. Although coal is the major item of cost, there are other expenses, such as labor, allowance for depreciation of plant equipment, and taxes, that must be charged off before any profit can be shown.

Under market conditions that have prevailed during the past few years, the cost of coal used at byproduct-coke plants has exceeded the value of the coke produced. It will be noted that virtually all of the increase in cost of coal has been absorbed by the increase in value of coke produced, as the value of the byproducts per ton of coke produced has declined since 1937. No data on total costs or profits have been collected, but the table indicates clearly the trend of the market.

PREPARATION AND SOURCE OF COAL

Washed and unwashed.—The quality of coal received is of paramount importance to the coke industry, for quality directly affects the yield, calorific value, and quality of coke and also materially affects efficient operation of the plant and costs of manufacture.⁸ Coals available for coke manufacture that contain an undue proportion of ash, sulphur, or other impurities are usually cleaned before being charged into ovens. In 1944, 32 byproduct- and 12 beehive-coke plants used coal that had been cleaned at mines, and 6 byproduct-coke plants charged into their ovens coal that was cleaned at the ovens. The quantity of washed coal charged into byproduct ovens increased 11 percent over 1943 and accounted for 28 percent of the total coal charged. Although the total amount of coal consumed in beehive ovens in 1944 declined from 1943, the quantity of washed coal charged increased 9 percent and was equivalent to 13 percent of the total compared with 11 percent for the preceding year.

Sources.—The Appalachian region extending from Alabama to Pennsylvania is the greatest reservoir of coking coal in the United States and supplied four-fifths of all coal used in the manufacture of byproduct coke in 1944. The principal States, in tonnage of coal furnished to byproduct-coke-oven operators in 1944, were Pennsylvania, supplying 37 percent; West Virginia, 35 percent; Kentucky, 14 percent; and Alabama, 8 percent. Although West Virginia ranked second to Pennsylvania in tonnage purchased, the distribution of its coal was far more widespread and moved to 17 other States. The principal consumer of Kentucky coal was Indiana, which received 44 percent of its total requirements from that State. The tremendous expansion in coal-carbonizing equipment in the Far West in 1944 accounts for the 87-percent increase in coking coal from Utah. Arkansas and Oklahoma were added to the list of States supplying coking coal.

¹Low-volatile—dry V. M. 22 percent or less and more than 14 percent; medium-volatile—dry V. M. 31 percent or less and more than 22 percent; high-volatile—dry V. M. more than 31 percent.

Blending.—During 1944, 75 of the 88 active byproduct-coke plants purchased coals of different volatile content. Both high- and low-volatile coals were purchased by 45 plants; high-, medium-, and low-volatile by 25 plants; high- and medium-volatile by 3 plants; and medium- and low-volatile by 2 plants. In addition, 9 plants used anthracite fines in their coal mix. Of the 13 plants that did not purchase coals of different volatile content, 10 purchased high-volatile and 3 medium-volatile coal. Table 24 shows the purchases, by States, of the coals used in the manufacture of byproduct coke, classified as to volatile content. In 1944, of the 95,939,290 tons of coking coals purchased, 67 percent was high-volatile, 13 percent medium-volatile, and 20 percent low-volatile, approximately the same ratio as for 1943.

YIELD OF COKE PER TON OF COAL

CONSUMPTION OF COKE

Consumption of byproduct and beehive coke in the United States in 1944 totaled 72,971,401 tons, an increase of 2 percent over 1943, the previous record high. Coke used in iron blast furnaces represented 78.2 percent of the total coke consumption.

According to figures compiled by the American Iron and Steel Institute, the quantity of coke used per ton of pig iron produced in 1944 advanced 9.2 pounds over the preceding year; and for pig iron, including ferro-alloys, the gain was 6.3 pounds. This increase was no doubt due to a number of variable factors including the increased content of the coke charged into blast furnaces.

The quantity of coke consumed in other ways (in foundries, in smelting nonferrous metals, in the manufacture of producer and water gas, in other miscellaneous chemical and industrial uses, and in domestic heating) amounted to 15,899,712 tons, an increase of 8 percent over 1943. Of the tonnage consumed in other ways, 41 percent was used in domestic heating, the second-largest trade channel for byproduct coke.

TABLE 29.—Coke consumed in manufacture of pig iron and for other purposes in the United States, 1913, 1918, 1937, and 1943-44, in net tons

Year	Total production	Imports	Exports	Net change in stocks	Indicated United States consumption ¹	Consumed by iron furnaces ¹		Remainder consumed in other ways

¹ Production plus imports minus exports, plus or minus decrease or increase, respectively, of net changes in stocks.

² From Report of American Iron and Steel Institute. Figures include coke consumed in manufacture of ferro-alloys.

³ Data not available.

TABLE 30.—Coke and coking coal consumed per net ton of pig iron made in the United States, 1913, 1918, 1937, and 1942-44

Year	Coke per net ton of pig iron and ferro-alloys ¹ (pounds)	Yield of coke from coal (per cent)	Coking coal per net ton of pig iron and ferro-alloys (pounds calculated)	Year	Coke per net ton of pig iron and ferro-alloys ¹ (pounds)	Yield of coke from coal (per cent)	Coking coal per net ton of pig iron and ferro-alloys (pounds calculated)
1913.....	2,172.6	66.9	3,247.5	1942.....	1,822.8	70.0	2,604.0
1918.....	2,120.7	66.4	3,193.8	1943.....	1,834.3	70.0	2,620.4
1937.....	1,830.6	70.3	2,604.0	1944.....	1,840.6	70.3	2,618.2

¹ From Report of American Iron and Steel Institute; consumption per ton of pig iron only, excluding furnaces making ferro-alloys, was 2,172.6 pounds in 1913, 2,120.7 in 1918, 1,806.7 in 1937, 1,791.4 in 1942, 1,800.6 in 1943, and 1,809.8 in 1944.

FURNACE, FOUNDRY, DOMESTIC, AND OTHER COKE

Tables 31 and 32 show the disposal, by major uses, of byproduct and beehive coke as reported by producers.

Byproduct coke.—In 1944, iron blast furnaces received 77 percent of all byproduct coke sold or used by producers. Furnace plants

supplied 96 percent of the byproduct coke delivered to blast furnaces compared with 92 percent in 1943. This increase was due largely to the additional coking capacities completed during the year at furnace plants. Sales of coke for furnace use by merchant byproduct-coke plants decreased 51 percent from the peak in 1943 when 8 percent of all coke shipped to blast furnaces came from merchant plants. The second largest coke consuming channel is the domestic trade, supplied mainly by merchant plants. In 1944, sales of domestic byproduct coke increased 35 percent over 1943 and totaled 6,443,329 tons, of which 77 percent was furnished by merchant plants. Sales of coke for foundry use and for other industrial purposes increased slightly from the preceding year.

Beehive coke.—The pattern of beehive-coke disposal followed in general that of previous years, 83 percent of all beehive coke sold or used going to iron blast furnaces in 1944. Unlike producers of byproduct coke who use the bulk of the output from their ovens, beehive producers in 1944 used but 11 percent of their output. Because of the need in certain areas for solid fuels for domestic heating, a considerable tonnage of run-of-oven beehive coke was sold for domestic use. This resulted in an increase of 170 percent in sales of domestic beehive coke over 1943 and amounted to 274,214 tons. Beehive coke sold for foundry use decreased 29 percent from 1943, and a drop of 8 percent was recorded in the disposal for other industrial uses.

³ Includes 387 tons valued at \$2,531 sold to financially affiliated corporations for other industrial use and 170,551 tons, \$1,244,596, for manufacture of water gas.

STOCKS OF COKE AND COKING COAL

Producers' stocks of byproduct coke increased 32 percent during 1944 and at the end of the year totaled 1,086,446 tons. Table 33 gives details of the total quantity of coke and breeze on hand at all coke plants, by States, on January 1, 1945. Stocks of byproduct furnace and foundry coke decreased slightly, whereas stocks of domestic coke increased 106 percent over 1943. The increase in stocks of domestic coke was due largely to Government limitations on deliveries during the fuel year 1944-45 and to adverse weather conditions that hampered transportation in December. Table 35 shows the stocks of coke on hand at producers' plants, by months, during 1943 and 1944.

Because of lack of available storage facilities and loading equipment at beehive-coke plants, stocks of coke on hand are usually very small. Producers' stocks of beehive coke varied only slightly from those of the preceding year and on January 1, 1945, totaled 38,239 tons.

Table 36 shows the stocks of bituminous coal at byproduct-coke plants, by months, for 1937 and 1942-44. In 1944 coal stocks remained rather constant throughout the year and on December 31 were equivalent to an average 24 days' supply compared with 25 days at the end of 1943. Stocks of coal were lowered by mine stoppages in 1943 and could not be built up during 1944 to a 30-day supply, which is considered the minimum required in wartime. A number of plants averaged less than a week's supply at certain times during the year, and the Solid Fuels Administration for War diverted thousands of tons of coal from byproduct-coke plants having more than a 30-day supply and from other industrial plants that were using coking coal for steam generation to plants with inadequate reserves. A summary of the regulation issued by Solid Fuels Administration for War covering byproduct coal is given under Government Control Measures in this report.

TABLE 36.—Stocks of bituminous coal at byproduct coke plants in the United States at the end of each month, 1937 and 1942-44

VALUE AND PRICE

The term "value" as used in this report means the value of coke at ovens. The greatest part of the coke produced in the United States is made in ovens operated by corporations, which not only mine the coal they use but also operate blast furnaces that consume the bulk of the output of their ovens. Under such conditions, fixing a value for coal charged and for coke produced is purely arbitrary. For example, at some establishments the cost of coke to the furnace department equals the cost of production; with others a margin of profit is added, or the cost is considered to be the market value.

The total value of all coke produced, by States, is shown in table 10 and was 11 percent higher than in 1943. Pennsylvania led all States in value and tonnage produced, accounting for almost one-third of the total value of the byproduct- and beehive-coke output.

The average receipts per ton of coke sold in 1944 increased sharply over those of the preceding year because of higher coal and labor costs. Receipts per ton of byproduct coke sold in 1944 increased over 1943 as follows: Furnace, \$0.18; foundry, \$0.86; domestic, \$0.42; and other industrial, \$0.69.

Average sales realization for beehive coke showed the following price increases per ton over 1943: \$0.42 for furnace, \$0.70 for foundry, \$0.84 for domestic, and \$0.56 for other industrial.

SHIPMENTS BY RAIL, WATER, AND TRUCK

Table 39 shows the quantity of byproduct and beehive coke shipped from producing plants by rail, water, and truck.

A large part of the byproduct coke produced is consumed by the producer in adjacent steel works and therefore is not loaded for shipment outside the plant. Total shipments of byproduct coke in 1944 amounted to 26,031,430 tons, or 39 percent of the total output. Railroads transported 85 percent of the total byproduct-coke shipments compared with 84 percent in 1943. In spite of tire and gasoline rationing, the percentage moved by truck increased 1 percent over 1943. Shipments by boat are relatively insignificant in the movement of coke, and in 1944 the quantity so moved decreased 2 percent below 1943.

The bulk of beehive coke produced near the mines is loaded at the plants for shipment to centers of consumption, and in 1944, 89 percent of the total output was transported from producing plants. Railroads transported 98 percent of all beehive shipments in 1944; truck and boat, 2 percent.

DISTRIBUTION OF BYPRODUCT AND BEEHIVE COKE

For practical purposes the terms "distribution" and "consumption" are used herein interchangeably. The total quantity of byproduct and beehive coke available for consumption in the United States, excluding imports, in 1944 increased 2 percent over 1943 and amounted to 73,035,439 tons. Deliveries to blast furnaces and export shipments for furnace use declined slightly from 1943. Shipments of coke to consumers for foundry use both in the United States and foreign destinations declined 93,796 tons from the preceding year. Shipments of coke for manufacturing water gas declined 27 percent from 1943; the decline is due to a change in the 1944 classification of coke consumed in the manufacture of water gas which is used in chemical synthesis from "water gas" to "other industrial". If this tonnage were added, the 1944 water-gas figure would be 6 percent higher than for the preceding year. Coke available for domestic heating within the United States increased 35 percent and export shipments 127 percent.

TABLE 40.—Summary of byproduct and beehive coke and breeze consumed in each State in 1944, in net tons

[Based upon reports from all United States producers showing destination of coke used by producer or sold in 1944. Does not include imported coke which totaled 63,004 tons in 1944]

EXPORTS AND IMPORTS

Shipments of coke to foreign countries in 1944 represented only 1 percent of the total output and amounted to 866,835 net tons, valued at \$7,334,309. This was a decrease of 13 percent in quantity, but because of the higher prices prevailing the decrease in value was only \$8,179. Over 94 percent of the total export shipments were destined to Canada, for the most part moving through the Buffalo and Michigan customs districts.

* Figures on exports and imports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Imports of coke supply an insignificant part of the Nation's requirements and are restricted to a few localities. The total tonnage imported in 1944 amounted to 63,004 tons, a decrease of 36 percent from 1943. Canada supplied all of the coke imported, the bulk of which entered through the Buffalo, Montana, and Idaho districts.

¹ United Kingdom of Great Britain and Northern Ireland.**WORLD PRODUCTION**

Data on world production of coke are not complete, but information obtained from various Government sources indicates that output in most of the major producing countries increased over 1943. In Canada, coke production continued the upward trend that started in 1939 and was 19 percent higher in 1944 than the previous peak established in 1943. In spite of heavy bombing of the Ruhr area of Germany, commencing in the summer of 1942 and continuing through 1944, estimated coke production for the 1943-44 coal year increased 639,000 metric tons over the preceding coal year. Of the total production shown in table 43 for Germany, including the Saar, in 1944, it is estimated that more than 66 percent was produced in the Ruhr. Data on 1944 production in Great Britain are not available; however, production in 1943 showed a decrease of 3 percent from the preceding year. Production in Free China is shown for the first time, and a decrease from 1943 is noted in the 1944 output. Production in Spain increased slightly over 1943 but fell short 3,222 tons of the peak established in 1940.

† Gas-house coke not included.

‡ In addition to countries listed coke is produced in Chosen and Japan, but data of production are not available.

§ Data not available.

¶ Coal year ended March 31 of year stated.

** Exports.

†† January to August, inclusive.

‡‡ Production of Free China.

§§ Excluding Sweden since October.

|| Excluding October 1939 East Upper Silesian production included.

¶¶ In Great Britain production of gas-house coke (including breeze), not included, is especially important and was 13,049,139 tons in 1938.

*** Figures for 1929 represent "hard" and "soft" coke made at collieries only—73,616 tons of "hard" coke and 799,888 tons of "soft" coke. Data for other years represent total "hard"

coke manufactured. In addition, "soft" coke made at collieries was as follows: 1938, 921,479 tons; 1941, 281,071; 1942, 246,648 tons.

§§ Sales of coke by Wankie Colliery for year ended August 30 of year stated.

|| Exclusive of Mexico.

MEDIUM- AND LOW-TEMPERATURE COKE

Salient statistics on coke and byproducts obtained by the carbonization of bituminous coal at medium- and low-temperature plants are shown in table 44. Although this process of treating coal is fundamentally the same as in high-temperature byproduct-coke ovens, the design and operating features of medium- and low-temperature ovens are radically different, and the resultant coke and byproducts produced differ in chemical and physical properties; for this reason, the Bureau of Mines has established a separate classification for this group of plants. Because only two companies operated before 1943, data for these plants were included with those for byproduct plants.

Gas (surplus).....		\$111,303
Total value of coke and breeze produced and byproducts sold.....		\$2,154,911

¹ Includes value of other byproducts of tar distillation at 1 plant.

Production of medium- and low-temperature coke in 1944 amounted to 223,691 tons. The average yield of coke per ton of coal carbonized was 61.53 percent compared with 71.01 percent for high-temperature byproduct ovens; however, the percentage of breeze recovered was higher, averaging 14.51 percent compared with 5.29 percent for the byproduct industry. This coke is not generally used for metallurgical

purposes, and as it is an excellent fuel for household heating 84 percent of the total output was used for domestic heating in 1944..

The principal byproducts of medium- and low-temperature carbonization plants are crude coal tar and gas. It is to be noted that the average yield of these byproducts per ton of coal charged differs greatly from that of high-temperature byproduct-coke ovens. Crude tar yield averaged 10.71 gallons compared with 8.13 gallons for byproduct ovens, whereas the gas yield was the reverse and averaged 7.06 M cubic feet compared with 10.68 M cubic feet. In 1944, the total value of coke and breeze produced and byproducts sold was \$2,154,911.

GAS-HOUSE COKE

The production of coke from coal-gas retorts in 1944 totaled 878,632 tons valued at \$7,078,113, an increase of 2 percent in output and 5 percent in value over 1943. Vertical retorts and miniature gas ovens furnished 55 percent of the output, and the remainder was produced in horizontal retorts. Gas-house coke was produced at 90 plants operating in 27 States compared with returns from 95 producers in the same States in 1943. In order of putput the leading States were Massachusetts, Wisconsin, New York, Pennsylvania, and Michigan; they supplied 67 percent of the total.

The disposal of gas-house coke in 1944 followed in general the pattern established in previous years, and 45 percent of the production was consumed at producing plants. Of the quantity used by producers, 48 percent was used for heating benches, 36 percent for making water gas, and the remaining 16 percent for making producer gas, raising steam, heating buildings, and other miscellaneous uses. The shortage of solid fuels for domestic purposes in certain areas directed attention to available supplies of gas-house coke. Sales for domestic use amounted to 423,675 tons (90 percent) of the total deliveries. Sales for use in the manufacture of water gas and other industrial purposes were not extensive and accounted for the balance—49,823 tons.

Additional data on coal-gas plants are given in Bureau of Mines Mineral Market Report M. M. S. 1280.

COKE-OVEN BYPRODUCTS

SUMMARY OF BYPRODUCTS

When coal is heated well above its decomposition temperature in byproduct-coke ovens it yields, in addition to "coke," the porous residue, a considerable quantity of gaseous material from which are recovered the principal byproducts—tar, ammonia, light oil, and gas. From these primary byproducts, a wide variety of materials essential to the national economy are manufactured by a chain of industrial

FIGURE 2.—Average yield of principal byproducts per net ton of coal carbonized in byproduct-coke ovens, 1915-44. Figures for light oil represent average at plants recovering light oil.

processes. By virtue of this fact, there exists a definite relationship between the coal-carbonization industry and countless other industries that depend directly or indirectly on this source of supply for raw material for their use. Crude coal tar, ammonia, light oil, and gas are the principal raw materials for the manufacture of perfumes, dyes, pharmaceuticals, explosives, fertilizers, plastics, and other chemicals required in the manufacture of aviation gasoline and synthetic rubber. The gross value of all byproducts sold increased 2 percent over 1943 and was equivalent to 39 percent of the value of the byproduct coke produced. This value does not include the value of breeze produced nor tar used as fuel by producers.

¹ Includes products of tar distillation conducted by coke-oven operators under same corporate name.² Softening point less than 110° F.³ Softening point over 160° F. Includes some medium pitch of tar reported by one producer.⁴ Includes gas used for heating ovens and gas wasted.⁵ Refined on premises to make derived products shown: 259,544,535 gallons.⁶ Total gallons of derived products.⁷ Ammonium thiocyanate, cyanogen sludge, dicyclopentadiene, hexane, phenol from sources other than tar distillation, residuals, sodium prussiate, sulfur, and vented vapors.⁸ Exclusive of value of breeze production, which was \$13,281,342 in 1944.

Crude coal tar and tar derivatives.—Production of crude coal tar increased 4 percent over 1943 and reached an all-time high of 767,-807,171 gallons. The principal uses of tar are as a raw material for the manufacture of coal-tar products, as a fuel for open-hearth furnaces or other metallurgical operations, and as a fuel under boilers. Of the total quantity sold or used by the producers for refining, coke-oven operators processed 26 percent on the premises compared with 22 percent in 1940, which reflects the expansion in tar-distilling facili-

ties that has been made at coke plants since the start of the war. The War Production Board granted exceptions to Conservation Order M-297 to some steel plants where a shortage of fuel oil existed so that 81 percent more tar was burned in 1944 than in 1943.

Ceiling prices on crude tar were continued throughout 1944 under provisions of Maximum Price Regulation 447, issued by the Office of Price Administration in 1943.

The constituents are separated from the crude coke-oven tar either in batch stills or by fractional distillation in continuous stills. Production of creosote, a derivative largely used for impregnating lumber, increased slightly over the output of the preceding year and reached 43,779,321 gallons. The value of sales of creosote accounted for 55 percent of the total revenue received by coke-oven operators from the sales of all tar derivatives. Tar-acid oil production and sales as such ranked next to creosote in quantity and value. Pitch-of-tar changed only slightly from the preceding year as regards output and was used primarily as fuel.

Ammonia.—Ammonia was recovered at 85 of the 88 active by-product-coke plants in 1944, 66 of which made ammonium sulfate and 23 ammonia liquor (4 plants produced both sulfate and liquor), some of which was purified in order to remove sulfides, carbonates, and pyridine. The total production of ammonia (NH_3 equivalent of all forms) amounted to 472,451,549 pounds, or 5.07 pounds per ton of coal carbonized. Fully 87 percent of the total ammonia recovered was converted to ammonium sulfate, which was sold for use as a fertilizer. Sales of ammonium sulfate, which remained under allocation throughout the year, totaled 1,553,923,139 pounds, approximately the same as the preceding year. However, the allocations of ammonium sulfate were considerably lower than production, and producers' stocks increased more than 143 percent during the year. To relieve the pressure of excessive stocks in the hands of producers, the War Production Board, in a letter dated November 19, notified all fertilizer manufacturers east of the Rocky Mountains that allocations of ammonium sulfate would be increased by one-twelfth above their original quota. The entire increase could be taken in January 1945 or, if the buyer preferred, distributed over the first quarter of the year.

The price of ammonium sulfate during the war period has remained unchanged under provisions of Maximum Price Regulation 205 established in 1942 and revised June 30, 1944.

Gas.—Approximately 17 percent by weight of the coals charged into high-temperature byproduct-coke ovens is recovered in the form of fuel gas. Usually about 37 percent of the gas output is used to heat the ovens, and the remainder is consumed by affiliated metallurgical works, neighboring industries, and public utilities. The yield of gas in 1944 remained the same as in 1943, but owing to the increased quantity of coal charged into ovens total output increased 5 percent over the preceding year and soared to a new all-time high. The gain made available a greater quantity of surplus gas, and that used or sold for industrial purposes and distributed through city mains increased 5 percent in volume and \$5,502,215 in value over 1943. The value of surplus gas was equivalent to 51 percent of the total value of all byproducts sold or used by the producers.

The average unit value of the surplus gas as reported by operators, which has declined steadily from \$0.187 per M cubic feet in 1938 to

\$0.150 in 1943, rose to \$0.152 in 1944. The average unit value of surplus gas sold or used by producers is governed largely by the ratio of gas sold for distribution through city mains, since this gas always commands higher prices than that used under boilers or in steel or affiliated plants.

Crude light oil and light-oil derivatives.—Crude light oil is a term used in the byproduct industry to designate the mixture of all those condensable products derived from the coking process, the boiling points of which do not exceed 200° C. It consists principally of benzol, toluol, and their homologs. The potential yield of crude light oil per ton of coal varies widely, depending on the quality of coal charged, design and condition of ovens, oven temperatures, coking time, and kind of scrubbing equipment. In 1944 the yield per ton of coal carbonized at individual plants recovering light oil ranged from 2.06 gallons to 4.04 and averaged 2.87 gallons compared with 2.83 gallons in 1943. Total output increased 7 percent over 1943 to 267,861,984 gallons. Production of benzol (all grades), the principal constituent of light oil, increased 8 percent over 1943. More than 87 percent of the benzol produced was refined into 1° and 2° grades, which are used principally for the production of cumene, employed in the enrichment of aviation gasoline, and of styrene, employed as an essential component in compounding synthetic rubber.

The production of toluol has increased steadily in recent years and in 1944 totaled 33,528,232 gallons. This output was but approximately one-fourth of the total output for the country, as production of toluol from the refining of petroleum has increased tremendously since 1942, and according to preliminary figures reported to the United States Tariff Commission the production from this source, exclusive of that produced under ordnance control, totaled 96,000,000 gallons in 1944.

The combined production of xylol, solvent naphtha, and other light-oil derivatives increased 2 percent over 1943. The prices for benzol, toluol, and xylol did not vary from the previous year; however, on July 15, 1944, the Office of Price Administration issued Amendment 66 to General Maximum Price Regulation which placed sales of benzol, toluol, and xylol, formerly exempted when sold for the manufacture of synthetic rubber and aviation gasoline, under price control at the level of March 1942. Sales of benzol, toluol, and xylol produced from petroleum and sales of benzol by the Defense Supplies Corporation remained exempt.

BYPRODUCT-COKE OVENS OWNED BY CITY-GAS COMPANIES (PUBLIC UTILITY PLANTS)

Production of coke at byproduct plants owned and operated by city-gas companies in 1944 decreased 2 percent below 1943 and was equivalent to 6 percent of the total byproduct-coke output.

At these plants, maximum production of coke-oven gas is generally desired, and more emphasis is placed upon the production of gas of proper analysis than upon the grade of coke obtained. Of the total coke-oven gas produced at public utility plants in 1944, 87 percent was distributed through city mains compared with 12 percent for all other plants. It will be noted in the following table that the average unit value of the surplus gas sold and used by public utility plants is considerably higher than at other plants. This is due largely to the great quantities of gas used by steel companies or affiliated plants operating coke ovens, and the value assigned for gas use is merely a credit value after manufacturing costs of coke and other byproducts are deducted.

In 1944, city-gas companies operated 15 byproduct-coke plants in 10 States. New York was the ranking State in number of city-gas plants, and the output of coke, gas, tar, and ammonia was 1,657,787 tons, 27,613,540 M cubic feet, 24,699,715 gallons, and 46,062,359 pounds, respectively.

A summary of the operations of city-gas or public utility plants in relation to the byproduct industry as a whole is presented in the following table:

SUMMARY

For the sixth consecutive year the fuel-briquetting industry exceeded the previous year's production and in 1944 reached a new high of 2,464,961 net tons. On the other hand, production in the packaged-fuel industry decreased in each of the past 4 years, mainly because of wartime shortages in materials and labor. Packaged-fuel production in 1944 dropped to 175,770 tons.

At the beginning of the war in 1939, the briquetting industry was utilizing 28.0 percent of its total capacity; by the end of 1944 it had geared its wartime production to 70.6 percent.

The manufacture of briquetting equipment continued restricted through 1944, subject to approval and priorities by the War Production Board; used equipment, however, was not subject to priorities. The Board² reported that some changes in control might be possible after the close of the war in Europe.

In February 1944, Solid Fuels Administrator Harold L. Ickes, in connection with his distribution program, urged the fuel industry wherever possible to substitute Pennsylvania anthracite fines, of which there is a large surplus, for bituminous coal, the supply of which was low. The briquetting industry's response to this suggestion has resulted in an increase in the use of anthracite in 1944 of 322,416 tons, or 83 percent over 1943, and a decrease of 152,127 tons, or 11 percent, in bituminous coal used.

Price control by the Office of Price Administration prevented the spiraling of briquet prices in World War II³ such as occurred in the first World War. However, some packaged-fuel operators reported that ceiling prices made profitable operation impossible.

¹ Directories of fuel-briquetting and packaged-fuel plants operating in 1944 and names of manufacturers of equipment will be furnished on request by the Bureau of Mines, Washington 25, D. C.

² Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

³ Data on employment and principal expenses in the manufacture of fuel briquets may be obtained from the Bureau of the Census.

Briquets made from charcoal, wood scrap, and fruit pits are not included in Bureau of Mines review.

Records on fuel briquets collected since 1907 and on packaged fuel since 1935 published in earlier reports of this series.

⁴ American Mining Congress, Construction Machinery Outlook: Weekly Information Service Bulletin, December 8, 1944, p. 5.

⁵ Minerals Yearbook, 1943, Chapter on Fuel Briquets and Packaged Fuel, p. 1041.

Technologic developments.—Research in fuel briquetting in 1944 was confined mainly to experiments by the Bureau of Mines⁴ towards a broader utilization of Pennsylvania anthracite fines in combination with bituminous coal. Research of this kind was suggested by the Solid Fuels Administration for War to relieve shortages of bituminous coal for domestic use. The admixture of anthracite fines to bituminous coal has been used extensively in fuel briquetting but not in packaged fuel; these tests, however, show that such mixtures can be used successfully in packaged fuel.

One packaged-fuel and two fuel-briquet plants designed primarily for the utilization of anthracite fines are now nearing completion. The two briquet plants, to be operated by the Reading Briquet Co. at Locust Summit and St. Nicholas, Pa. (estimated construction cost approximately \$2,500,000), will have a combined annual capacity of 500,000 tons and plan to use an admixture of approximately 90 percent anthracite fines and 10 percent bituminous coal; production is expected to start in 1945.⁵ The packaged-fuel plant (estimated construction cost approximately \$400,000), to be operated by the White Glove Packaged Fuel Division of the Blaw-Knox Co., at Philadelphia, Pa.,⁶ utilizing a combination of approximately 80 percent Pennsylvania anthracite fines and 20 percent bituminous low-volatile coal, also expects to be in production in 1945. The three plants are Government-financed.

Investigations on briquetting various Illinois coals using the Piersol-designed press and process⁷ were continued in 1944 with special reference to contour of the briquet and the metallurgical composition of briquetting dies. Dies have been contoured to produce double rows of 1.2- by 1.5-inch notched ribbon briquets, 1.5-inch pillow briquets, and a single row of 3-inch pillow briquets and 3-inch semipillow briquets; of these, the last-named is considered the preferred contour.

Postwar outlook.—After the close of the war fuel-briquet production probably will continue high, and packaged fuel undoubtedly will recapture its former place in the fuel industry. This assumption is based upon the fact that past records for both these types of domestic fuel—generally high-grade in quality and of established popularity—show demand usually exceeding supply and the product sold as soon as available.⁸ Machine manufacturers report new and improved types of equipment and contracts for installations when War Production Board restrictions are lifted. Supplies of kraft paper used in packaging coal cubes probably will continue tight in 1945⁹ but will become available in larger quantities after the war.

Survey Rept. of Investigations 31, 1933, 70 pp.; Briquetting Illinois Coals Without a Binder by Impact: Illinois State Geol. Survey Rept. of Investigations 37, 1935, 75 pp.; Smokeless Briquets: Impacted Without Binder from Partially Volatilized Illinois Coals: Illinois State Geol. Survey Rept. of Investigations 41, 1936, 30 pp.

⁸ Black Diamond, Chicago and Central Western Market—Twin Cities and Northwest: Vol. 112, No. 2, January 22, 1944, p. 52; vol. 112, No. 4, February 19, 1944, p. 60; vol. 112, No. 7, April 1, 1944, p. 44.

⁹ Neubrech, W. Leroy, Pulp and Paper Getting Scarcer: Domestic Commerce, vol. 33, No. 4, April 1945, p. 20.

The erection of the two Reading Briquet Co. plants and that of the White Glove Packaged Fuel Division of the Blaw-Knox Co. in Pennsylvania (to use Pennsylvania anthracite in combination with bituminous low-volatile) will extend the fuel-briquet and packaged-fuel markets still further.

FUEL BRIQUETS

Salient statistics of the fuel-briquetting industry from 1940 to 1944 are summarized in the following table. Production and value from 1917 to 1944, inclusive, are shown graphically in figure 1.

FIGURE 1.—Production of fuel briquets, output per plant, number of plants in operation, and average value per net ton, f. o. b. plant (Central States), 1917-44.

Salient statistics of the fuel-briquetting industry in the United States, 1940-44

[Data regarding packaged fuel are given separately at end of this chapter]

¹ Production plus imports minus exports.² Less than 1,000 tons.

Production.—The output of fuel briquets advanced in 1944 to a new high—2,464,961 tons valued at \$18,434,579—a 14-percent increase in tonnage and a 22-percent increase in value over 1943. The industry responded remarkably in its efforts to meet increased fuel demands notwithstanding the shortages of manpower and raw fuels and the staying hand of priorities on new equipment.

Production rose to 71 percent of the capacity of the 30 plants active in 1944, reported as approximately 3,494,000 tons (see capacity analysis in following pages). Briquets were produced in 15 States in 1944, with Wisconsin again leading and West Virginia, Missouri, and Pennsylvania following in order. (Wisconsin also led in packaged-fuel production in 1944.) All States except two showed increases over 1943, with Pennsylvania and Missouri outstanding. Fuel briquets have been produced in Missouri every year since 1907, but production was comparatively small until 1942. Output for the 13 States (other than Wisconsin and Missouri) cannot be shown separately without revealing data for individual plants.

Production of fuel briquets in the United States, 1943-44

1944.....	3	252, 286	1, 910, 384

Bagging of bulk briquets at the plants, reported by seven operators in 1944, is a merchandizing feature only, used for convenience and cleanliness in the delivery of the fuel; one operator, however, reported wrapping several hundred tons of cubes—a small part of his total production—in 10-pound packages suitable for burning in the package if desired.

As briquets are used almost entirely for domestic space heating in the United States, production is normally highly seasonal; but in 1944, as in 1943, the monthly output continued fairly constant throughout the year. Of the 30 plants active in 1944, 24 operated every month and only 3 less than 10 months. According to the Weather Bureau,¹⁰ the coldest weather in 1944 in the briquet-consuming States occurred in January, in the Dakotas, Minnesota, Iowa, and Wisconsin, and is reflected in greatly increased shipments¹¹ of briquets to these States. A relatively mild winter was experienced in other parts of the country.

Monthly production of fuel briquets in the United States, 1942-44, in net tons

Month	1942	1943	1944	Month	1942	1943	1944

Value.—The trend of fuel-briquet prices in the past 5 years is indicated best in this review by the average values in the Eastern, Central, and Pacific Coast States, as shown in the last three columns of the first table of this report. These are the values received by producers for the total product (exclusive of delivery charges) and not the prices paid by consumers; retail prices in certain cities are shown in a separate table.

¹⁰ Baldwin, J. L., *The Weather of the United States: U. S. Dept. of Commerce Monthly Weather Review*, vol. 73, January 1945, p. 6.

¹¹ See following table for "Shipments of fuel briquets of domestic manufacture, 1943-44, by States of destination, as reported by producers, in net tons."

The total value of fuel briquets produced in 1944 was \$18,434,579, f. o. b. plant—an increase of \$3,286,470, or 21.7 percent, over 1943.

Prices.—The following monthly fuel-briquet prices, available for 15 cities for 1944, except as otherwise indicated, represent cash sales to household customers for 1-ton lots (2,000 pounds) delivered at the curb or into the bin if no extra charge is made. The monthly periods covered extend from the 15th of one month to the 15th of the succeeding month. The changes in prices during the year are few and generally reflect local adjustment to ceilings allowed by OPA, based upon variations in costs.

Retail fuel-briquet prices per net ton in 1944, by cities and months

Number of plants.—Thirty briquetting plants reported production in 1944, and all but two of these were active also in 1943. One plant, idle in 1943, resumed production late in 1944, and one plant, the Ecco Manufacturing Co., Pine Grove, Pa., started operating in January 1944. The Great Lakes Carbon Corp. discontinued briquetting operations at its St. Paul, Minn., plant in May 1944. The plants of the Scranton Collieries Corp. at Scranton, N. Dak., and of the Calkins Pressed Fuel Co., at Renton, Wash., have been permanently abandoned; the Scranton plant had been idle for many years, but the Renton plant was active from 1934 to 1942. Four plants were idle in 1944—one each in Connecticut and Minnesota, idle for 5 years or more, and one each in Ohio and Texas, idle since 1941, when a small production was reported.

Of the five plants reported under construction in 1943, only the Ecco Manufacturing Co., at Pine Grove, Pa., started production in 1944; one in Texas was idle in 1944, and construction on the other three is not yet complete.

Seven plants reported under construction in 1944 are as follows:

Briquetting plants reported under construction in 1944

Capacity of plants.—The following table gives comparative data for the past 8 years and reveals the greater utilization of the total capacity of the active briquetting plants—from 28.0 percent in 1938 to 70.6 percent in 1944. The 1944 production was close to three times that in 1938, with virtually stationary capacity in the interim. Eight plants, each of which produced over 100,000 tons in 1944, supplied 1,743,591 tons, or 70.7 percent of the total production, utilizing 70.5 percent of the combined capacity of this group. Twelve plants, each with an annual capacity of 100,000 tons or more, furnished 2,079,563 tons, or 84.4 percent of the total 1944 production, utilizing 71.9 percent of their combined capacity.

Annual capacity and production of active briquetting plants in the United States, 1937-44

	Active plants		Production

	30	3,493,900	2,464,961	70.6	100.0

¹ 1 of these plants operated only 3 months of year.² 1 of these plants operated only 1 month of year.

The average output per plant rose from 58,000 tons in 1942 to 77,000 in 1943 and to 82,000 in 1944. Twenty-four plants operated every month in 1944 and produced 2,085,554 tons, or 85 percent of the total.

The largest capacities as well as largest productions in 1944 were reported by the Berwind Fuel Co. and the Stott Briquet Co. Inc., for their plants at Superior, Wis.

Raw fuels.—As shown in the following tables, seven kinds of raw fuels entered into the manufacture of fuel briquets in 1944, and 11 types of briquets were made from these fuels (either alone or in combination); the quantities of raw fuels used and tonnages of each type of briquets produced are shown wherever possible without revealing data on individual operations.

The notable increase in the use of Pennsylvania anthracite fines, both in the Eastern and Central States, particularly in combination with bituminous coal in 1944, is directly the result of the urging of the Solid Fuels Administration for War for wider utilization of the huge surplus of these anthracite fines to offset shortages in the bituminous supply. To assist the SFAW in its campaign for increased use of anthracite fines, OPA announced that briquet producers, who before November 23, 1943, used only bituminous coal, would not be required to reduce their maximum prices for briquets by the decrease in costs resulting from the substitution of anthracite for bituminous coal.¹²

There was also a large increase in the use of the hard coals of Arkansas in 1944, principally at briquetting plants in Arkansas, Minnesota, and Missouri.

Classification of plants and production of fuel briquets in the United States, by kinds of raw fuel used, 1942-44

Raw fuel used	1942			1943			1944		
	Plants	Briquets produced		Plants	Briquets produced		Plants	Briquets produced

¹ Includes a relatively small tonnage of petroleum coke of a type exempt from wartime allocation in 1943.

Petroleum-coke briquets were again made in 1944, as wartime restrictions on its use as domestic fuel were rescinded on October 24, 1944.¹³

In the following table showing production with reference to supply of raw fuel, the greatest gain in output of briquets in 1944 over 1943 occurred at plants at or near coal mines, principally at plants in the Central States that obtain their raw fuel from hard-coal mines in Arkansas.

Production of fuel briquets, 1943-44, grouped according to location of plants with reference to supply of raw fuel

Location of plant	1943		1944		Change in 1944

¹³ Coal Dealer, War Production Board Freezes Stocks of Petroleum Coke: Vol. 39, No. 7, November 1942, p. 23. War Production Board Petroleum Coke Conservation Order M-212, March 1943. Black Diamond, Chicago and Central Western Market: Vol. 113, No. 9, October 28, 1944, p. 57.

Ten operators using anthracite and one using bituminous coal reported that the raw fuel is washed before it is manufactured into briquets.

Binders.—Asphalt binders remain the preferred type and were used by 24 plants that produced 84 percent of the fuel briquets made in 1944. Three plants used, respectively, asphaltic and coal-tar pitches combined, asphalt and starch combined, and starch. In 1944, as in 1942 and 1943, three plants used no binder; two of these briquetted the carbon residue from the manufacture of oil gas and one used low-volatile bituminous coal.

Approximately 144,000 tons of asphaltic types and small quantities of starch and coal-tar pitch were used as binders in 1944 in the manufacture of fuel briquets.

Seventy percent of the total production of fuel briquets in 1944 was made with binders ranging from 5 to 7 percent of the raw fuel used, as compared with 38 percent of the production in 1943 and 31 percent in 1942.

No operators reported recarbonization of the briquets after leaving the presses.

Classification of briquetting plants in the United States, 1942-44, by percentage of binder used

Ratio of binder to raw fuel (by weight)	1942			1943			1944

	28	2, 163, 998	100. 0	31	2, 464, 961	100. 0

¹ 1 plant made both pillow and cylindrical shapes; hence the sum of these items exceeds the total of the number of plants active in 1944.

Shipments.—The following table of shipments to States of destination indicates the wide use of fuel briquets in the United States. Produced in 15 States in 1944, they were shipped from 12 of these States of origin into 35 States and the District of Columbia, and were exported principally to Canada; the entire production of 3 of the smaller States was consumed within those States. Shipments within the United States in 1944 exceeded those of 1943 by 16 percent; more than half of the production was shipped direct to Minnesota, Wisconsin, North Dakota, Michigan, and South Dakota. The relatively small difference between production in 1944 (2,464,961 tons) and shipments within the United States (2,278,480 tons) represents briquets exported, used at plants for fuel, and stocks on hand at the beginning or end of 1944.

Shipments of fuel briquets of domestic manufacture, 1943-44, by States of destination, as reported by producers, in net tons¹

¹ Shipments include resales that might have been shipped to Canada or to other States of destination. For official export statistics see table "Briquets exported from the United States, 1943-44, by countries of destination and customs districts."

Shipments by States of origin cannot be shown, as there are only one or two plants in each producing State except Wisconsin and Missouri, and the individual operations would thus be revealed. However, the widespread distribution across State lines from centers of production to States of destination in 1928 and 1936 is shown graphically in Minerals Yearbook, 1937 (p. 965, fig. 65). In comparison with the data used as a basis for the 1936 graph, 1944 showed large increases in production of plants in Illinois, Michigan, and West

Virginia and extension of their markets to other States and to Canada. The comparison further shows Indiana, Colorado, and Texas eliminated in 1944 as producing States, and Idaho, Wyoming, Colorado, Tennessee, Texas, and Louisiana as receiving no shipments of briquets during that year; however, production and shipments for these States since 1936 have been small and intermittent.

Generally, rail shipments represent consumption at distant points, and shipments by truck show local and nearby consumption.

Direct shipments of fuel briquets by rail and truck, 1943-44, as reported by producers, in net tons¹

¹ Includes shipments outside the United States.

² Includes local deliveries.

³ In addition, 27,225 tons used as fuel at plants.

Imports and exports.—A small tonnage of fuel briquets was imported into the United States from Canada in 1944. Figures for imports of briquets since 1919, first year of record, are included in annual volumes of Mineral Resources and Minerals Yearbook.¹⁴ Virtually all exports¹⁵ of fuel briquets in 1944 were destined for Canada.

*World production.*¹⁶—Recent information on the production of briquets since 1938 in Germany—the world's largest briquet-producing country—shows the output in 1944 to have reached a total of 68 million metric tons, an increase of 33 percent over Germany's 1938 production and approximately 3 million tons more than the entire world's known production of briquets in that year. Data on production in other countries have been meager since the beginning of the war in 1939.

*World production of fuel briquets, 1938-44, by countries, in metric tons*¹

¹ In addition to countries listed briquets are produced in Canada, Czechoslovakia, and New Caledonia but data on output are not available.

² Data not available.

³ Data for year ended March 31 of year stated.

⁴ Beginning October 1939, figures include production from East Upper Silesia.

⁵ Beginning October 1938, figures include production from Sudetenland.

⁶ Includes packaged fuel as follows—1938: 146,012 tons; 1939: 195,504; 1940: 258,105; 1941: 244,797; 1942: 229,560; 1943: 195,592; 1944: 159,455 tons.

⁷ Total incomplete; it represents sum of figures given in table only.

PACKAGED FUEL

Packaged fuel is the trade name applied by the industry to a combination of briquetting and packaging of screenings compressed into 3- or 4-inch cubes and wrapped (six or eight in a package) in sturdy paper and sealed with gummed tape.

The phenomenal growth in popularity of packaged fuel from 1935 through 1940 and its decline since that time are strikingly illustrated in figure 2. The production of packaged fuel in 1944 continued its downward trend from 1940, when the industry was at its height with a production of 284,513 tons and 106 plants in operation. In 1944, as in previous war years, scarcity of labor and materials and restrictions on the manufacture of new equipment caused production to decline and closed many plants.

⁸ Data since 1913 published in earlier reports of this series.

The outstanding development in the packaged-fuel industry in 1944, and one that probably will revolutionize that field, is the plan sponsored by the Federal Government at the request of the Solid Fuels Administration for War¹⁷ to use Pennsylvania anthracite fines as raw fuel in packaged-fuel manufacture. The suggestion has proved feasible, as shown by extensive experiments by the Bureau of Mines,¹⁸ and such a packaged-fuel plant, now under construction in Philadelphia,¹⁹ is expected to be in production in 1945 by the White Glove Packaged Fuel Division of the Blaw-Knox Co. The plant will have an annual capacity of 150,000 tons and will use approximately 80 percent anthracite fines in combination with 20 percent bituminous low-volatile coal.

Processes.—No new presses or types of machinery were reported in use by the packaged-fuel industry in 1944. In 1944, 62 of the 68 operators used the Eberling process;²⁰ 2 operators used Leemon²¹ equipment; 2 used Glenn-Smith²² equipment; and the Johnson Coal Cubing Co., Inc.,²³ of Detroit, Mich., and one other plant used equipment designed by the latter company.

Salient statistics of the packaged-fuel industry from 1940 to 1944 are summarized in the following table.

Salient statistics of the packaged-fuel industry in the United States, 1940-44

[Data regarding fuel briquets are given separately at beginning of this chapter]

Year	Production (net tons)			Value of production	Plants in operation	Average output per plant (net tons)	Average value per net tons, f. o. b. plant	
	Eastern and Pacific Coast States	Central States	Total				Eastern and Pacific Coast States	Central States
1940.....	7,519	276,994	284,513	\$2,391,922	106	2,684	\$10.12	\$8.36
1941.....	9,549	260,295	269,844	2,471,567	103	2,620	10.95	9.09
1942.....	7,553	245,465	253,048	2,540,087	89	2,843	10.74	10.02
1943.....	4,970	210,635	215,605	2,866,733	72	2,995	11.15	10.96
1944.....	3,788	171,982	175,770	2,053,343	68	2,585	12.26	11.67

¹ Eastern States; no production in Pacific Coast States in 1943 and 1944.

Production and value.—The 68 plants active in 1944 produced 175,770 net tons with a value of \$2,053,343 (see fig. 2). Production decreased 18.5 percent from 1943 and total value decreased 13.2 percent; output declined in 9 of the 11 producing States. Michigan lost top rank in the industry to Wisconsin, principally as the result of the fire in July 1944 at the plant of the Johnson Coal Cubing Co., Inc., in Detroit, formerly the largest operator. (The plant, down for 4 months, has been rebuilt and operations were resumed in November 1944.) The

Total United States.....	72	215,605	2,366,733	68	175,770	2,053,343

¹ Included under "Undistributed"; Bureau of Mines not at liberty to publish figures.

² Includes States entered as "(¹)" above.

³ Maine, 1; Pennsylvania, 1; and Virginia, 3.

The values, by States, represent the average per ton received by operators in 1943 and 1944 and show a general increase in average realization at the plant in 1944; advances were prevalent in all but two of the other producing States, but these cannot be shown because there were fewer than three operators in each of these States. The values do not represent the price per ton to the consumer, as many plants sell both to retailers and consumers, but rather the average per ton received by producers on the total product (exclusive of delivery charges). The value at the plant comprises cost of coal at the mine, freight rate, direct and indirect manufacturing costs, and profit.

Average value received per net ton of packaged fuel, 1943-44, by States ¹

State	1943	1944	State	1943	1944
Illinois.....	\$12.48	\$12.54	Ohio.....	\$10.89	\$10.90
Michigan.....	10.57	11.08	Virginia.....	11.27	11.18
Minnesota.....	12.55	13.28	Wisconsin.....	10.55	11.46

¹ Includes only those States where there were 3 or more plants in both years.

Thirty-one of the sixty-eight plants active in 1944 operated each month of the year and produced 75 percent of the total production; 31 operated 6 to 11 months, and 6 less than 6 months. Output during the year followed its usual seasonal pattern.

Monthly production of packaged fuel in the United States, 1942-44, in net tons

Month	1942	1943	1944	Month	1942	1943	1944

July.....	7,688	7,772	5,377		253,048	215,605	175,770

Number of plants.—In 1944 the number of plants producing packaged fuel dropped to 68, the lowest since 1937, when there were 64 (the largest number was 106 plants in 1940). Sixty-three of these sixty-eight plants also were active in 1943, and over one-third of these are in the Detroit and Cleveland areas and contribute about 30 percent of the total production. Four additional plants equipped with used Eberling equipment began operating in 1944, and one plant under construction in 1943 went into production in January 1944. Twenty-two plants were idle in 1944 (8 of these were active in 1943); lack of labor and materials, scarcity of coal, and inability to operate without loss under OPA price ceilings were among the reasons given for idleness. Two companies reported plants under construction in 1944 (to start operations in April 1945)—a small plant in Detroit, Mich., and the large Government-sponsored plant of the White Glove Packaged Fuel Division of Blaw-Knox Co., at Philadelphia (discussed in the beginning of the packaged-fuel section of this report).

Activity in number of packaged-fuel plants in the United States, 1939-44

Year	Active	New	Idle	Out of business	Year	Active	New	Idle	Out of business
1939.....	103	29	11	9	1942.....	89	4	16	8
1940.....	106	16	15	14	1943.....	72	5	23	9
1941.....	103	7	8	14	1944.....	68	14	22	7

¹ All in Michigan and active in 1944.

² 11 in Michigan, 3 each in Indiana and Missouri, 2 each in Ohio and Wisconsin, and 1 in Washington.

³ 4 in Ohio and 1 each in Illinois, Maine, and Michigan; 1 of these was active in 1944 and 1943 and 6 were idle in 1943.

Capacity of plants.—The following table gives comparative data for the past 8 years and points out the large number of small plants in the packaged-fuel industry. In 1944 25 plants produced less than 1,000 tons each, contributing 8,655 tons, or 4.9 percent of the total production, and utilizing 14 percent of the combined capacity of this group. There were 45 plants, each with an annual capacity under 5,000 tons, that produced 48,040 tons, or 27.3 percent of the total production, and utilized 40 percent of their combined capacity.

Conversely, among the larger plants, four produced 62,095 tons—about one-third of the total 1944 production and two-thirds of their combined capacity.

Annual capacity and production of active packaged-fuel plants in the United States, 1937-44

25,000 tons or more.....	1	92,000	62,095	67.5	35.3
	68	428,600	175,770	41.0	100.0

¹ 2 of these plants operated only few months late in year.

The average output per plant declined from approximately 3,000 tons in 1943 to 2,600 in 1944. Thirty-one plants (less than half of the plants active in 1944) operated every month throughout the year and produced 131,110 tons, or 75 percent of the total.

The largest capacity was reported by the Johnson Coal Cubing Co., Inc., Detroit, Mich., followed by the Cleveland Cliffs Iron Co., Green Bay, Wis.

Raw fuels.—Six kinds of raw fuels entered into the manufacture of packaged fuel in 1944. The use of bituminous slack decreased from 97 percent of the total raw fuels in 1943 to 90 percent in 1944. Packaged fuel made from petroleum coke—which in 1941 amounted to 18 percent of the total raw fuels used—is again appearing on the market, as wartime restrictions on its use as domestic fuel were rescinded on October 24, 1944.²⁴ A small tonnage of Pennsylvania anthracite in combination with bituminous slack was used by a packaged-fuel operator in Detroit, Mich.

The proposed utilization of over 100,000 tons of Pennsylvania anthracite fines²⁵ in the manufacture of packaged fuel in 1945 by the White Glove Packaged Fuel Division of Blaw-Knox Co. in Philadelphia will bring about changes in production centers and open new markets in the East.

Raw fuels used in making packaged fuel in the United States, 1942-44

Raw fuel	1942		1943		1944	
	Plants	Net tons	Plants	Net tons	Plants	Net tons
Bituminous:						
Low-volatile.....	79	210,761	69	206,059	65	156,388
High-volatile.....	4	4,655	2		3	316
Pennsylvania anthracite.....					1	
Semianthracite.....	2	34,969	2	6,613	2	17,157
Petroleum coke.....	11		12		7	
Coke breeze.....					1	
	96	250,385	75	212,672	79	173,861

¹ These plants reported a relatively small tonnage of petroleum coke of a type exempt from wartime allocation in 1943.

² In 1942, 5 plants made more than 1 kind and 2 used mixtures of these fuels; in 1943, 1 plant made 2 kinds and 2 plants used mixtures of these fuels; in 1944, 7 plants made 2 kinds and 4 plants used mixtures of these fuels. Hence the number of items exceeds the total number of active plants in the respective years.

Eight types of packaged fuel were made in 1944, as follows:

Classification of plants and production of packaged fuel in the United States in 1944, by kinds of raw fuel used

Raw fuel used	Plants	Packaged fuel produced	
		Net tons	Percent of total
Bituminous:			
Low-volatile (exclusively).....	61	151,626	86.3
High-volatile (exclusively).....	2		
Mixture of bituminous low- and high-volatile.....	1	12,265	7.0
Mixture of bituminous low-volatile and Pennsylvania anthracite.....	1		
Mixture of bituminous low-volatile and petroleum coke.....	1		
Mixture of bituminous low-volatile and coke breeze.....	1		
Semianthracite (exclusively).....	2	11,879	6.7
Petroleum coke (exclusively).....	6		
	75	175,770	100.0

¹ 7 plants made 2 types of packaged fuel; hence the sum of these items exceeds the total number of plants active in 1944.

²⁴ See footnote 13.

²⁵ See par. 3 of packaged-fuel section of this report.

In 1944, about 124,000 tons (71 percent of the total raw fuels) were shipped-in slack from the mines and from the Lake docks; the remainder represents yard screenings. Thirteen of the sixty-eight operators used shipped-in slack exclusively, 26 used yard screenings, and 29 used both shipped-in slack and yard screenings.

Cubes measuring 3 to 3½ inches were made at 51 packaged-fuel plants; 4-inch cubes were made at 20 plants, of which 3 made cubes in two sizes.

Of the 68 active plants, 23 reported wrapping the cubes by machine, 17 by hand, and 28 a combination of machine and hand. Sixty-two plants wrap 6 cubes to a package, 5 plants wrap 8 to a package, and only 1 reported a package of 4 cubes. Fifty plants make up packages weighing under 11 pounds, and 21 make packages of 11 to 16 pounds; of these, 3 plants make up packages of two weights.

Only one plant reported sales of packaged fuel in bulk (unwrapped), amounting to less than 25 tons.

Binders.—Cornstarches totaling 1,029 tons were used as binder by 66 plants, which produced 136,111 tons of packaged fuel, or 77 percent of the total production in 1944; of these, 13 reported using 10 to 14 pounds of starch binder per ton of raw fuel, 29 used 15 pounds per ton, 23 used 16 to 20 pounds, and 2 reported using over 20 pounds of binder per ton. Asphalt alone was used by two plants; and one plant making petroleum-coke cubes used a combination of starch and asphalt. No cement binder was used in 1944.

Classification of packaged-fuel plants in the United States, 1943-44, by type and percentage of binder used

Type of binder	Plants		Ratio of binder to raw fuel (by weight)	Plants	
	1943	1944		1943	1944
Starch.....	67	66	Less than 0.5 percent.....		
Starch and asphalt.....	1	1	0.5 and less than 1 percent.....	57	56
Asphalt.....	2	2	1 and less than 2 percent.....	11	11
Cement.....	3		2 and less than 3 percent.....	1	
			3 and less than 5 percent.....	2	
			5 percent and over.....	2	2
	173	169		173	169

¹ 1 plant made 2 kinds of cubes using starch binder for one and starch and asphalt for the other; hence the sum of these items exceeds the number of active plants.

Shipments.—Local sales (called for by passenger car or delivered by truck) accounted for 79 percent of the 1944 total sales; other than local (by truck to points in Wisconsin, Minnesota, and Michigan), 14 percent; and by rail (to points in Wisconsin, Michigan, and Minnesota), 7 percent.

Shipments of packaged fuel, by method of movement, 1942-44, in net tons

PEAT

By J. A. CORGAN AND GOLDEN V. CHIRIACO

SUMMARY OUTLINE

	Page		Page
Summary.....	1022	Uses.....	1023
Reserves.....	1022	United States Government specifications.....	1024
Production.....	1022	Imports.....	1024
		World production.....	1025

SUMMARY

According to reports received by the Bureau of Mines, 57,987 short tons of peat, valued at \$524,521, were produced in the United States in 1944. Although this figure represents a minor drop from the 1943 output of 60,002 short tons, valued at \$491,460, it remains slightly more than half the peak United States production of 107,261 short tons in 1918.

The continued shortage of manpower has been the principal factor in the steady decline in peat production since 1941, and operations at many of the peat bogs have been discontinued until after the war.

Imports of peat moss, curtailed sharply since 1940 on account of the war, totaled 64,428 short tons, valued at \$1,916,794 in 1944 compared with 59,427 tons, valued at \$1,577,388, in 1943. As no exports are reported, the quantity available for domestic consumption in 1944 amounted to 122,415 tons, a slight increase over the 119,429 tons available in 1943. Approximately 97 percent of the peat produced was used for soil improvement and in mixed fertilizers.

A directory of names and addresses of operators who reported 1944 production to the Bureau of Mines has been prepared and will be furnished, upon request, to those who may be interested.

Reserves.—Peat, an integral part of the natural resources of the country, is found in about half of the States. An estimate of 13,827,-000,000 tons has been calculated as air-dried peat.¹

Minnesota, Wisconsin, and Michigan combined contain 75 percent of the reserves; 14 percent of the country's total is in Florida; and the rest is distributed through the New England and Pacific Coast States.

PRODUCTION

The 1944 production of 57,987 short tons, reported to the Bureau of Mines by 35 producers operating in 17 States, is comparable with 60,002 tons produced in 1943 by 37 producers in 17 States. Many operators reported that production had dropped considerably because of their inability to procure sufficient labor; whereas others, forced to close their plants altogether because of the labor situation, reported that they expect to resume operations after the war.

¹ Soper, E. K., and Osbon, C. C., The Occurrence and Uses of Peat in the United States: Geol. Survey Bull. 728, 1922, p. 92.

The average value per ton in 1944 was \$9.05, an increase of 10.5 percent over the 1943 value of \$8.19. Production and value for 1939-44 are shown in the following table.

Peat produced in the United States, 1939-44

Year	Short tons	Value		Year	Short tons	Value	
		Total	Average per ton			Total	Average per ton
1939.....	55,483	\$362,066	\$6.53	1942.....	71,500	\$516,887	\$7.23
1940.....	70,097	516,865	7.37	1943.....	60,002	491,460	8.19
1941.....	86,503	657,556	7.60	1944.....	57,987	524,521	9.05

Figure 1 illustrates graphically the trend in production and value of peat from 1908 to 1926 and from 1934 to 1944. No data are available for 1927 to 1933, inclusive, as the Federal Government made no canvass of the peat industry for those years.

FIGURE 1.—Quantity and value of peat production in the United States, 1908-44; no data available for 1927-33.

In 1944 the producing States, in order of output, were New Jersey, Illinois, Michigan, Pennsylvania, California, Florida, New York, Iowa, Maine, Wisconsin, Texas, Minnesota, Ohio, Washington, Georgia, Massachusetts, and New Hampshire. In 1943 Illinois led and was followed by New Jersey, New York, and Pennsylvania, the position of the other States varying also from that in 1944.

Peat humus, produced in 12 States, comprised 54 percent of the total production; reed or sedge peat, produced in 9 States, 37 percent; and moss peat and other, produced in 6 States, 9 percent.

USES

Reports continued to indicate that most of the peat sold in this country is used for soil improvement. In 1944, 75 percent was sold for this purpose, 22 percent was used in mixed fertilizers, and 3 percent was sold for other uses, including litter for barns and poultry yards. Peat is used also as packing for fruits, vegetables, shrubs, and fragile articles. No sales of peat for fuel purposes were reported.

In some European countries peat is used extensively as fuel. In the United States, except for regional emergencies, it has not been used for this purpose on a commercial scale because of plentiful supplies of higher-grade fuels.

Moss peat was collected for surgical dressings during the World War of 1914-18, at which time 595,540² moss-peat pads were prepared in this country, under the direction of the American Red Cross, and used in military hospitals both here and in Europe. Most of the peat came from Maine, Washington, and Oregon. Peat has not been used for this purpose during the present war because of available facilities for making surgical dressings from cotton, of which the supply has been ample.

United States Government specifications.—The Federal Government purchases a certain amount of peat provided it meets the required specifications. These specifications may be obtained from the Procurement Division, United States Treasury Department, Washington, D. C.

IMPORTS³

Imports in 1944, all of which came from Canada, totaled 64,428 short tons, valued at \$1,916,794. Before 1939 most of the peat imported came from Germany. In 1938 Germany supplied 36,381 short tons, valued at \$525,564; in the same year, the Netherlands and Sweden together supplied 21,836 tons, valued at \$348,252. The opportunity for increasing output, presented to producers in the United States by the decline in imports from other countries, has been thwarted to a great extent because of difficulties in obtaining necessary labor and materials.

The average value per short ton of imported peat was \$29.75 in 1944, compared with \$26.54 in 1943.

Peat moss imported for consumption in the United States, 1939-44

WORLD PRODUCTION

Restrictions imposed by wartime conditions have made it difficult to obtain data on production of peat in foreign countries. The latest available data are given in the following table.

World production of peat, 1939-44, by countries¹

SUMMARY

The marketed production of natural gas in 1944 is estimated to have increased 11 percent over 1943 to 3,780,232 million cubic feet, under the influence of a sustained high level of industrial production and record income payments. Domestic consumption was 10 percent, commercial consumption 9 percent, and total industrial 11 percent greater than in 1943.

The scarcity of other fuels, or more urgent demands for them, contributed to the volume of sales of natural gas, which was used as a substitute fuel in some localities. On the other hand, curtailment of industrial use was necessary in a few areas where capacity to deliver gas was unequal to peak load requirements during extremely cold weather. The major pipe-line systems undoubtedly operated at a higher percentage of their total annual capacity (load factor) in 1944 than in any previous year. Their major problems stemmed from the conflict between the growing demands of war-stimulated markets and restricted means with which to supply them.

Of the industrial uses, all expanded in 1944 except fuel at portland-cement plants, which contracted 31 percent owing to curtailment of cement production. Consumption at carbon-black plants increased sharply (17 percent) after 3 years of decline as the demand for carbon black mounted rapidly to record levels.

The average value of natural gas at the wells is estimated to have increased to 5.4 cents per thousand cubic feet in 1944 from 5.2 cents in 1943, extending the slow rise that began in 1941. Major production gains continued to center in the southwestern fields, where values are below the national average. However, the trend of values remains upward in virtually all producing districts.

¹ In this report the term "billion" is equivalent to 1,000,000,000 and "trillion" to 1,000,000,000,000, according to United States usage.

The indicated value at points of consumption of all gas marketed in 1944 is estimated to have declined to 21.8 cents per thousand cubic feet from 22.3 cents in 1943. Domestic and commercial average values continued the decline which since 1938 has amounted to about 8 percent and 15 percent, respectively. In the same period average consumption per domestic meter increased 28 percent to 54,900 cubic feet in 1944, and consumption per commercial meter increased 60 percent to 263,500 cubic feet. The average value of miscellaneous industrial gas (excluding field and carbon black) was only about 2 percent less in 1944 than in 1938, but the average use per consumer gained 94 percent to about 41.2 million cubic feet.

³ Federal Power Commission: Figures include gas other than natural, impossible to segregate; therefore shown separately from main table.

⁴ Exclusive of oil- and gas-field operators.

⁵ Figures not yet available.

FIGURE 1.—Production and value of natural gas in the United States, 1916-44.

The total value of marketed production at the wells has increased 80 percent since 1938 to about \$204,133,000 in 1944, and the total at points of consumption has gained 64 percent to \$821,310,000.

Exports to Mexico, which have grown in each year since 1938, reached a new record of about 13,900 million cubic feet in 1944. An application to construct a new line from South Texas to Monterrey, Mexico, was rejected by the Federal Power Commission early in 1945.

The number of consumers of natural gas of all types except oil- and gas-field users and carbon-black manufacturers amounted to about 11,492,000 in 1944, or 3 percent more than in 1943.

LAW AND ADMINISTRATION

Expanding requirements for war production, with the attendant problems of fuel supply and transportation, placed a heavy load upon the gas utilities in 1944. A limited control of gas distribution was exercised by Government action to protect essential users during the period of greatest demand.

The Office of War Utilities ordered 60 natural-gas companies that obtain gas from the Panhandle Eastern Pipe Line Co. to stop deliveries between February 15 and March 15, 1944, to all consumers having facilities for using fuels other than natural or liquefied petroleum gas. The order affected companies operating in Missouri, Michigan, Illinois, Indiana, Ohio, and Kentucky. The gas thus released was diverted to improve the supply for eastern market areas where war industries were facing curtailment or shut-down for lack of fuel. It has been estimated that restrictive measures reduced industrial use of natural gas about 15 billion cubic feet in the Appalachian area below the volume that would have been consumed, had it been available.

The gas shortage in that region prompted the Federal Power Commission to grant certificates for the construction of the Tennessee Gas & Transmission Co. line from South Texas to West Virginia and the War Production Board to allocate the necessary critical materials as a war measure.

On September 22, 1944, the Federal Power Commission made known its intention to investigate the conservation and utilization of natural gas, involving a study of the extent of reserves, types of use, competition with other fuels, and related matters.

The announcement produced a vigorous reaction from officials of producing States (particularly in the Southwest), from the gas industry, and from the petroleum industry, which was involved because of the close association of natural gas with petroleum production. Widespread discussion of the problems relating to gas conservation followed among these groups and in the public press. In response to the invitation of the Federal Power Commission to the States and other interested parties to file statements of their views and relevant statistical studies, several States and a number of industry groups began to prepare material for presentation at public hearings scheduled for late in 1945 at convenient points in gas-producing States.

Renewed interest in State laws applicable to oil and gas production was indicated by the introduction of numerous bills in the legislatures of important producing States, accompanied by debate of controversial issues and analysis of existing laws directed particularly toward an appraisal of those clauses bearing upon operating practices in the production of gas. A decision of the Supreme Court of Texas affirmed the power of the Railroad Commission to enforce the ratable taking of gas from wells and to adjust correlative rights of producers.

GROSS PRODUCTION

The gross production of natural gas in 1943 is estimated to have increased 11 percent over 1942 to 4,942,560 million cubic feet. Gains were indicated in most producing States, led by Texas, California, and Louisiana. As in 1942, the only large decline in output occurred in Illinois, where a high percentage of the gas is produced with oil and is not marketed.

The production from gas and condensate wells was about 3,208,780 million cubic feet in 1943 or 11 percent greater than in 1942. Of this total, Texas contributed 51 percent, Louisiana 16, West Virginia 7, Oklahoma 5, and California 5.

Available evidence indicates that the volume of gas produced from oil wells increased to 1,733,780 million cubic feet in 1943 from 1,568,810 million in 1942, influenced primarily by a 9 percent gain in oil production. Accurate records of the gas produced with oil are generally kept only for those areas in which close control of reservoir performance is maintained or to cover that portion of the gas which is utilized for purposes other than the production of oil. Therefore, the statistics of this type of gas production are incomplete. A comprehensive study of gas : oil ratios could be used to closely approximate the rate of production of gas from oil wells. Such a study is under consideration in Texas.

Gross production and disposition of natural gas in the United States, 1942-43, by States, in millions of cubic feet

¹ Marketed production plus quantities used in repressuring, stored in ground, lost, and wasted (see footnote 2).

² Includes gas (mostly residue gas) blown to the air and transportation losses but does not include direct waste on producing properties, except where data are available.

³ Revised figures.

⁴ Includes gas transported from other States.

⁵ North Dakota, South Dakota, Tennessee, Utah, and Virginia.

In 1943 repressuring or pressure-maintenance with natural gas was reported in 16 States, an addition of one (Colorado) to the 1942 list. A significant increase in California resulted from greater efforts to conserve oil-field gas for use in oil production and for growing markets that threaten to outstrip present sources of supply in the southern district. Further gains in Texas and Louisiana were related primarily to expansion of cycle-plant operations in condensate-type fields. In the oil fields of most other States (particularly in Illinois and New Mexico) moderate growth in gas injection operations was indicated.

The total volume of gas returned for repressuring in 1943 was 824,803 million cubic feet, 10 percent more than in 1942 and the largest quantity so used in any year.

The storage of natural gas in depleted natural reservoirs for delayed marketing was reported in 13 States in 1943, 2 more than in 1942. The total quantity of gas stored, however, declined to 18,953 million cubic feet from 21,024 million in 1942. Smaller net amounts of gas were stored in several Western States and in all of the States in the critical Appalachian region. These declines do not indicate that the magnitude and importance of the functions of gas storage in marketing operations have lessened. Most reservoirs equipped for storage were filled to, or near, desired operating pressures in prior years. Heavy withdrawals of gas in the cold months of 1943, particularly in November and December, reduced the net gain in volume of gas in storage to a small percentage of the total input during the summer months.

Information from the Office of War Utilities indicates that in the Appalachian region the total quantity of natural gas in storage and available to meet peak-load demands reached a new high of 65.7 billion cubic feet on September 30, 1944, or 2.3 billion cubic feet above the seasonal peak of 1943. A total of 26.7 billion cubic feet of natural gas was added to storage during the summer of 1944, and withdrawals during the calendar year amounted to 24.5 billion. Deliveries of gas from fields in the Southwestern States were of value to the storage program in this area. Such deliveries increased from about 8 billion cubic feet in 1943 to 41 billion in 1944.

The estimated amount of gas lost and wasted (684,115 million cubic feet) in 1943 was about 9 percent above the 1942 total, primarily because of operations in Texas, where both oil production and gas marketing increased materially. The waste in Illinois was reduced 43 percent in 1943 with the further decline in flush oil-producing capacity. In Arkansas and California steps were taken to utilize more of the available gas or to return it to productive formations below ground.

MARKETED PRODUCTION

The quantity of natural gas marketed reached a new peak in 1943, conforming to the trends of industrial production and national income. Under the wartime economy the demand for natural gas has increased so rapidly in many industrial areas that total sales have been limited during winter months by transmission capacity rather than by the desire of consumers to buy.

A total of 3,414,689 million cubic feet was marketed during the year—12 percent over the 3,053,475 million recorded in 1942. Increased production was reported in all States except Indiana, Mississippi, New York, South Dakota, Utah, and Virginia, none of which has a large output. New York produced less than one-fourth the volume recorded in 1938 and Mississippi about one-tenth the volume in 1939 when local supplies began to fail. Texas, Louisiana, California, Oklahoma, and West Virginia maintained that order of rank as in 1941 and 1942. These five States produced 82 percent of the total output in 1943. Texas, Louisiana, and California gained 13 percent, Oklahoma 6 percent, and West Virginia 4 percent over the 1942 production.

¹ Less than 0.05 percent.

² Includes 1,453,000 M cubic feet piped to Mexico.

³ Includes 32,000 M cubic feet piped to Canada.

⁴ Includes 99,000 M cubic feet piped to Canada.

⁵ Includes 9,626,000 M cubic feet piped to Mexico.

The average value of gas at the wells in 1943 continued the upward trend begun in 1941 and was 5.2 cents—0.1 cent above the 1942 average. The average value at points of consumption in 1943 reflected the increase in industrial consumption and lower prices. It was 22.3 cents per thousand cubic feet compared with 22.7 cents in 1942.

In 1940 and in 1943 the five principal southwestern gas-producing States supplied 68 percent of the total marketed production in the United States, at average values at the wells of 2.1 cents and 2.8 cents per thousand cubic feet respectively. The share of the Appalachian group of five States in total marketed production declined only slightly in this period (from 15 to 14 percent) as the average field price advanced from 14.8 cents to 15.6 cents.

WELLS

The total of gas-well completions in 1944 reached 3,069, or 34 percent above 1943, as drilling revived after 2 years of decline. Progressive relaxation of well-spacing controls by the Petroleum Administration for War and improved availability of materials helped to stimulate development. More new wells were reported in 17 States than in 1943, with outstanding gains in Texas, West Virginia, Pennsylvania, and Oklahoma. Drilling was active in the major dry-gas fields of the Southwest and in a number of condensate fields in the Gulf Coast region. New productive capacity was developed for expanding markets for natural gas and the liquids obtained from it.

The number of producing gas wells increased during 1943 from 56,150 on January 1 to 57,200 on December 31. The indicated number of gas wells abandoned or shut in during 1943 was 1,240, of which over 80 percent was in the five eastern producing States. These States had about 78 percent of all the gas wells in the United States on December 31, 1943.

TECHNOLOGIC DEVELOPMENTS

Chemical processing of the constituents of natural gas has emerged during the war from comparative obscurity to play prominent roles in a number of essential industrial programs. Its potentialities, as sketched in recent technical literature, appeal to the imagination, for the promises of growth and even of revolutionary change involve many and varied fields of production.

Although the volume of natural gas and associated liquefied gases utilized as chemical raw materials has increased rapidly since 1941, the total is very small compared with that sold for fuel. The impact of all of these chemical activities upon the established business of marketing natural gas has therefore been scarcely felt. More significant economic change has doubtless occurred in some branches of the chemical industry (as distinguished from petroleum refining), where the scale of production is relatively small and unit values of products are high.

From the standpoint of the producer of natural gas the most important chemical developments are doubtless those that have made possible the conversion of methane into motor fuel and other useful products at currently competitive costs. It has been announced that equipment is now commercially available that will produce a high-grade gasoline at 5 cents per gallon from natural gas costing 5 cents per thousand cubic feet, the yield being about 4 gallons per thousand cubic feet. Other liquid hydrocarbons, including 100 cetane Diesel fuel, and waxes of unusual character can also be produced at commercial costs. This and similar processes may provide a profit motive for the conservation of natural gas and refinery vapors by opening important new markets to these materials. Several experimental pilot plants are in operation, and commercial installations are expected to follow.

Much of the current utilization of natural gas as a raw material for chemicals results from the demand for hydrogen, which enters into many industrial processes, including the manufacture of synthetic ammonia, hydrochloric acid, and methanol; the hydrogenation of oils of petroleum and other origins; and fabrication of metals. A cheap supply of hydrogen is obtained from thermal decomposition of natural gas or its reaction with steam, with byproducts of carbon black in the first instance and carbon dioxide in the second.

In the manufacture of synthetic rubber, butane and butylene are processed to produce butadiene, and propane is cracked to ethylene, an intermediate in styrene production. Whole series of new substances are being created from light hydrocarbons by such chemical techniques as regenerative cracking, chlorination, nitration, and oxidation controlled by catalytic action.

The development of Diesel engines that are convertible under full load from oil to gaseous fuel, with a claimed efficiency about 30 percent higher than older engines operating on gas, may lead to a broader use of gas for power generation. This type of prime mover would be valuable at locations where natural gas is available at low cost, except during periods of peak demand, when a stand-by oil supply could be substituted.

The adaptability of carbon black (a product of natural gas), and rubberlike materials with which it is compounded, to broader fields of

usefulness has resulted from recent intensive research. Thus a larger demand for carbon black has developed in "rubber" and in the growing field of plastics as a filler and pigment.

The "pressure-weld" method came into prominent use in pipe-line construction for the first time in 1944. It involves clamping the ends of pipe lengths that are to be joined in a patented device in which they are heated by application of oxyacetylene flames. The ends, when raised to a closely controlled temperature below the fusion point, are forced together under pressure to form a strong joint or weld. Savings in labor and total cost, as compared with other welding methods, are claimed.

One of the most interesting technical developments in the industry in recent years came to a tragic end in 1944. The liquefied-gas storage plant that began operations in February 1941 as an auxiliary gas supply to meet the peak-load requirements of Cleveland, Ohio, was demolished by fire with heavy loss of life and property.² Although this unique project had been successful technically and financially, reconstruction is not contemplated at present. Means of caring for the city's gas needs have been provided by new pipe-line connections with western gas supplies and additional underground gas storage capacity.

POSTWAR OUTLOOK

The vigorous growth-trend of the natural-gas industry is indicated by the graph of marketed production (fig. 1). The quantity of gas marketed in 1943 was 120 percent above that in 1933 and exceeded the predepression peak in 1930 by 76 percent. For the United States as a whole the reserves of gas appear to be adequate for many years, and markets exist for more gas than is being distributed at present. A comparison of the average values of natural gas at points of consumption with costs of competing fuels since 1939 suggests that the competitive cost position of natural gas has not deteriorated but, on the contrary, has improved for some applications. Therefore, on economic grounds alone, the expectation of continued expansion in natural-gas sales in the period following the war appears amply justified.

Referring again to figure 1, it may be seen that the upward course of the marketed-production curve has been interrupted only three times since 1916. On each occasion the cause was a sharp decline in the industrial production of the country, which was reflected by a relatively small contraction in natural-gas sales. If industrial activity and national income drop sharply after hostilities cease, a material decline in gas marketing doubtless would occur; however, with the passing months this possibility appears more likely to exert only a minor, short-lived influence upon the demand for gas.

The current efforts to restrict by political action the transportation of natural gas from several southwestern producing States to other States for consumption if successful, would retard or prevent the expansion of natural-gas distribution, particularly in the Eastern and Northern States. It has been stated that such restriction of interstate commerce is beyond the powers granted the States under the Federal Constitution.

² Seibel, C. W., Elliott, M. A., Brown, F. W., Artz, R. T., and Berger, L. B., Reports on the Investigation of the Fire at the Liquefaction, Storage, and Regasification Plant of the East Ohio Gas Co., Cleveland, Ohio, on October 20, 1944; Bureau Mines Rept. of Investigation. In press.

Also bearing upon the question, however, will be the results of the investigation of the natural-gas industry by the Federal Power Commission, briefly discussed in the Law and Administration section of this chapter. If the conclusions drawn from its study of the end uses to which natural gas may be put in the public interest call for the elimination of some types of large-scale industrial consumption, the restraint thus placed upon future growth of the industry would apply with comparable force to the interstate movement of gas.

The average value of natural gas at the wells has risen slowly since 1940, which marked the end of a consistent decline of many years duration. The reversal in trend probably reflects the gradual absorption of tremendous amounts of available distress gas, mostly in "dry" gas fields, for which no market was provided as rapid development of productive capacity proceeded. The dynamic expansion of gas markets has been the fundamental cause of this desirable change from the standpoint of conservation and of the owners of gas reserves.

It is expected that a firm trend in values of natural gas at the wells will continue to be supported by growing utilization of gas for consumption and for improving the efficiency of oil production. Measures of control applied from outside the gas industry might modify the rate of progress and the forces that determine the price of gas in the field.

The pressure exerted by competing services and by State and Federal regulatory authorities upon domestic and commercial rates for natural gas has influenced the declining average cost to these consumers during the past 10 years. Continuation of this force may be expected to foster a growing demand from small consumers and to shift more of the financial burden of maintaining gas service to the large industrial users, whose unit cost of gas may be expected to rise, except in areas of surplus gas supply.

The result of these trends will be to increase the proportionate amount of gas used for domestic and commercial purposes relative to total marketed production.

REVIEW OF FIELD DEVELOPMENTS, BY STATES

Arkansas.—Figures of production and consumption of natural gas in Arkansas in 1944 were submitted by L. L. Jordan, chief engineer, Arkansas Oil and Gas Commission.

There were 177 gas wells producing in 25 fields in the State at the close of the year compared with 192 wells in 23 fields in 1943. Two gas wells were completed in the northern gas fields in 1944 and 3 in 1943.

The Columbia and Texarkana pools—both gas-producing areas in southwestern Arkansas—were closed during the greater part of 1944 for lack of a market.

Natural-gas production increased 35 percent from 59,655 million cubic feet in 1943 to 80,667 million in 1944. Of the 1944 output, 61,028 million (76 percent) came from the controlled and 14,809 million (18 percent) from the uncontrolled oil and gas fields of southern Arkansas, and 4,830 million (6 percent) from the northern gas fields. Comparative figures for 1943 are: 47,782 million (80 percent), 6,243 million (11 percent), and 5,630 million (9 percent), respectively. These amounts indicate a 40-percent increase in output from the southern and a 14-percent decrease in output from the northern fields.

The gain in southern Arkansas is due largely to completion of the McKamie Gas Cleaning Co. plant and to development in the Dorcheat-Macedonia field.

Total gas vented was 21 percent of production in 1943 and 26 percent in 1944. The greater part is gas impractical to gather because of its volume and physical characteristics.

Gasoline plants processed 31,801 million cubic feet of gas from controlled fields and 14,809 million from uncontrolled fields in 1944 compared with 24,809 million from controlled and 6,243 million from uncontrolled fields in 1943. Fifty-six percent of the residue gas was sold commercially in 1944 compared with 55 percent in 1943.

Gas from the southern fields was distributed in 1944 as follows: Field fuel 4,038 million cubic feet, gas lift 252 million, gasoline-plant fuel 3,305 million, shrinkage at gasoline plants 5,932 million, sold 31,930 million, recycled or returned to formations 10,512 million, and vented 19,868 million. These figures represent gains over the 1943 record in all classifications except gas used for gas lift, which decreased 70 percent.

Gas in northern Arkansas was sold for light and fuel.

California.—About 10 exploratory and 50 development gas wells were drilled in California during 1944 in an effort to meet an ever-increasing demand for natural gas.

The following information on natural-gas developments was taken from a report supplied by E. F. McNaughton, Railroad Commission of California.

Prospecting for new dry-gas wells increased in the northern part of the State during the year, and there were several gas discoveries. A promising one was the Suisun Bay field in Solano County, where 300 feet of gas sand was found in some tests. No information as to the extent of the productive area was given. Gas was also found in the Chico area of Butte County, in the Ord Bend field 11 miles west of the city of Chico in Glenn County, and in the southeastern corner of the same county. A discovery 9 miles northwest of the Trico field (11 miles west of the city of Delano) was apparently in the same trend as the Trico field. One new area was 18 miles northwest of the Thornton field (22 miles south of Sacramento), and another was in the Kirby Hills region of Solano County. The Thornton gas field was extended a mile to the west.

Fourteen wells were drilled in the Rio Vista gas field in 1944, and pipe-line connections were made to facilitate larger withdrawals of gas.

The most important pipe line built during the year was one from the La Goleta underground storage project to the Los Angeles market. It was the key line for most of the new gas lines built in southern California. During times of peak demand the gas will flow toward Los Angeles, and in off-peak seasons it will flow toward the field for storage. Four new wells were drilled to increase the rates of injection and withdrawals, and new compressor units were installed. It is expected that the line will make available 160 million cubic feet of gas daily above the capacity of lines formerly serving the region. Part of the supply will come from a recently discovered reserve in the lower zones of the Ventura Avenue field which existing lines would not have been equipped to transport. The line will tend to obviate the necessity of selling high-grade surplus gas in off-peak seasons to industries that could use lower-grade fuels.

The Playa del Rey storage field has proved to be a satisfactory project. A study conducted by the Railroad Commission and the Division of Oil and Gas found that the only important migration of gas was into an area where satisfactory agreements for its return were in practice. The field was valuable in making an adequate supply of gas available to meet peak demands during the winter of 1944.

Growth in the civilian population and increased demands of war industries caused a material increase in the use of natural gas in 1944. Dry-gas production totaled 186,778 million cubic feet, a 21-percent increase over the 1943 record. The Rio Vista gas field furnished 84 percent of the total dry-gas output in both 1943 and 1944. A total of 361,859 million cubic feet of gas was distributed by gas companies in 1944. Domestic and commercial consumption took 161,599 million cubic feet; industrial consumption, including company use, 181,716 million; unaccounted-for gas, 13,509 million; and net storage, 5,035 million. In addition to the above, 60,656 million cubic feet were delivered to oil fields and to other consumers.

Pressure maintenance is being practiced increasingly in the oil fields. The amount of casinghead gas available for distribution will therefore be decreased, but the output of oil probably will be increased.

R. M. Bauer, gas-supply supervisor, Southern California Gas Co., supplied the following information.

A total of 8,656 million cubic feet of gas was stored in the Buena Vista Hills, La Goleta, and Playa del Rey fields in 1944—37 percent over the 6,341 million stored in 1943 and 34 percent over the 6,442 million stored in 1942.

Production in California totaled 549,431 million cubic feet in 1944 (not including 69,495 million used for repressuring), a 16-percent gain over that reported in 1943. Of the total, 186,778 million cubic feet were produced by gas wells and 362,653 million by oil wells. Comparative figures for 1943 are 154,323 million cubic feet from gas wells and 318,654 million (not including 48,105 million used for repressuring) from oil wells. Unconserved gas comprised 9,928 million cubic feet in 1944 compared with 6,892 million in 1943. Utilized production and net gas withdrawn from storage in 1944 was distributed as follows, in millions of cubic feet: Domestic and commercial use, 160,208; gasoline-plant shrinkage, 26,995; field and plant fuel, 89,444; refinery and pump-station fuel, 69,830; fuel at steam electric generating plants, 48,719; company use, 4,900; other industrial uses, 121,919; and gas unaccounted for by gas companies, 13,604.

California retained first place among the States in the number of consumers using natural gas in 1944.

Colorado.—J. R. Schwabrow, acting supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo., reports only one gas development in Colorado during 1944. It was a deep test on the White River dome in the north central part of Rio Blanco County drilled to 7,005 feet in 1943 and plugged back for tests in 1944. A productive capacity of 500,000 cubic feet or more of gas and a small amount of condensate were found in the Wasatch and Mesa Verde formations between 5,626 and 5,909 feet. This well and a small one completed at 5,987 feet in the same area in 1930 were shut in during the year. Most of the shallow wells in the field have been abandoned as nonproductive.

A pilot plant for separating carbon dioxide from oil was built in the North McCallum field. Tests showed that the gas could be profitably returned to formations. A combined plant equipped to extract the oil and return the carbon dioxide to the reservoir at the rate of possibly 30 million cubic feet daily will be put in operation in 1945.

Hiawatha field with a 15-percent and Powder Wash with a 5-percent decline from the 1943 record furnished 95 percent of the marketed production in Colorado in 1944, compared with 96 percent in 1943. Production by fields, in millions of cubic feet, follows: Hiawatha 3,158, Powder Wash 1,450, Thornburg 218, Berthoud 43, and Craig 3. The volume of casinghead gas from the Wilson Creek oil field, where 8 oil wells were completed, increased. The gas : oil ratio is about 285 cubic feet per barrel.

Natural-gas production in 1944 totaled 5,987 million cubic feet, a 3-percent decline from the 6,148 million reported in 1943. Marketed production declined 11 percent from 5,460 million cubic feet in 1943 to 4,872 million in 1944. Gas used for recycling or repressuring totaled 453 million cubic feet, compared with 273 million in 1943. There were 207 million cubic feet used in the field and 455 million lost, gains over the 1943 record of 18 and 90 percent, respectively.

Illinois.—A report by Alfred H. Bell, geologist, and David H. Swann, associate geologist, Illinois State Geological Survey, gives the following information relative to natural-gas developments in Illinois during 1944.

The only gas completions were three in the Bridgeport sand of the Russellville field in Lawrence County. This compares with five completions in the Russellville field and one in the Ayers field in 1943.

Production from gas wells constituted little more than 1 percent of the total output in Illinois in 1944. Gas from the Russellville and Ayers gas fields and some residue gas from natural-gasoline plants in the Salem and Loudon oil fields is marketed for domestic and industrial uses outside of the petroleum industry. The gas thus utilized was between 2 and 3 percent of a total output of 45 to 60 billion cubic feet.

Natural-gasoline plants processed about 22 billion cubic feet of casinghead gas from the Benton, Dale-Hoodville, Loudon, New Harmony, Salem, and Southeastern oil fields. About one-half of the 15 to 17 billion cubic feet of residue gas was returned to formations, one-third was used as plant or lease fuel, 725 million cubic feet were marketed commercially, and over 2 billion were burned in flares.

In areas where there are no pipe-line connections or gasoline plants, it is estimated that over half of the gas produced is used for fuel on the leases. Less than one-sixth of the total production in Illinois in 1944 was vented or burned in flares. These figures show great improvement over the 1943 record, when a large part of the output was reported as wasted.

Indiana.—A report by Otis V. Freeman, acting State geologist, states that 28 gas wells were drilled in Indiana during 1944. The largest one was in the Rockport field. Its initial output was 2,680,000 cubic feet daily.

The most productive gas fields in the State are the Rockport, Spencer County, the Greensburg, Decatur County, and the Unionville, Monroe County.

No estimate of gas production for 1944 was given.

The small marketed production of natural gas has been relatively stable since 1916. In recent years, increased oil-production activity has helped sustain gas output against the declining capacity of sources of dry gas.

Kansas.—L. B. Taylor of the Conservation Division of the Corporation Commission of Kansas states that there was extensive drilling in the Hugoton field, and additional reserves were discovered in the Lake City area of Barber County in 1944. The Kansas Power & Light Co. has applied for a permit from the Federal Power Commission to connect the new field to its distribution system. No new transmission lines from Kansas fields were built during the year.

Production was reported from 30 fields in 1944 compared with 25 in 1943. Chitwood was the new field reporting the largest yield (1,853 million cubic feet). The Hugoton field ranked first in output, with Medicine Lodge second and Otis third. The Hugoton area gained 31 percent over 1943 (62 percent of the State's output in 1944 compared with 52 percent in 1943). Medicine Lodge increased 5 percent and Otis decreased 9 percent. The Cunningham (Viola) field declined from 7,773 million cubic feet in 1943 to 5,709 million in 1944 and Burrton from 6,442 million to 2,465.

Production by major fields in billions of cubic feet follows: Hugoton, 83.0; Medicine Lodge, 14.4; Otis, 12.1; Cunningham (Viola), 5.7; Burrton, 2.5; Chitwood, 1.9; Cunningham (Arbuckle), 1.2; McLouth, 1.2; and Alden, 1.2. East Kansas production is estimated at 5,700 million cubic feet in 1944 compared with 6,300 million in 1943, a 10-percent decline. Gas sales totaled 134,703 million cubic feet in 1944, 10 percent over the 122,089 million reported for 1943.

Kentucky.—Mrs. Louise B. Freeman, assistant State geologist, Department of Mines and Minerals, reports that there were no significant changes in the natural-gas industry in Kentucky during 1944.

Of 229 gas wells drilled in the State during the year, only 2 were in western Kentucky. The remainder were in more or less proved areas in 9 counties in the eastern fields. These figures compare with 210 wells drilled in 17 counties in 1943. Pike County maintained first place in number of gas completions as compared with the 1943 record, and Floyd and Martin Counties displaced Knott in second rank. Completions in eastern Kentucky in 1944 were as follows: Pike County 80, Floyd 43, Martin 43, Knott 30, Jackson 9, Johnson 8, Magoffin 7, Clay 6, and Knox 1.

The new wells added 2,603,000 cubic feet daily to the total productive capacity. Counties having the largest daily average were: Martin 674,000 cubic feet, Pike 529,000, Magoffin 491,000, Floyd 316,000, and Johnson 242,000. Over one-half of the State gas production comes from the Chattanooga black shale.

There were 3,000 to 3,100 producing gas wells in eastern Kentucky in 1944 with a total daily average production of from 175 to 200 million cubic feet. No figures of production for the year are available, but a slight increase is indicated in spite of shortages of manpower and materials.

Louisiana.—Gas-well completions in 1944 numbered 82, of which 67 were in the Northern and 15 in the Southern district. The most active fields were Monroe with 40 completions, Lisbon 6, and Holly Ridge 4.

Exploratory drilling in North Louisiana resulted in the discovery of two distillate fields—Benton in Bossier Parish, producing from the Cotton Valley formation at 8,000 feet, and Tremont in Lincoln Parish, producing from the Cotton Valley below 9,000 feet. Distillate production in the Cotton Valley field, Webster Parish, was extended and a new pay sand opened. New gas fields were found in Bienville, De Soto, Lincoln, and Webster Parishes. The discovery of the first oil in Richland Parish in the northeastern part of the State opened an extensive new area to oil and gas exploration.

In South Louisiana, four distillate fields and two dry gas fields were discovered. The distillate fields were: Bayou Penchant in Terrebonne Parish, College Point in St. James, South Lake Charles in Calcasieu, and Laurel Ridge in Iberville. These fields all produced from the Miocene at depths between 9,900 and 10,800 feet. New dry-gas fields were reported at West White Lake, Vermilion Parish, and Houma, Terrebonne Parish, also producing from the Miocene below 10,000 feet.

The largest cycle plant in the country commenced operations in the Erath distillate field, Vermilion Parish, in April 1944, after about 2 years devoted to engineering studies of the field, organization of all owners of fee and leases for unit operations, and actual construction. The processing of slightly more than 200 million cubic feet of gas daily yielded initially about 16,000 barrels per day of light liquid products. Almost 90 percent of the volume of gas produced is returned to the productive sands, of which there are about 19 in all, at the unusually high injection pressure of 4,600 pounds or more.

Two furnace-type carbon-black plants were built in 1943 to operate on waste casinghead gas in the Eola and Ville Platte fields. This type of loss from oil production was thereby reduced.

Louisiana natural-gas production totaled 799.5 billion cubic feet in 1944, a gain of 100 billion over 1943, according to data released by the Louisiana Conservation Commission.

Michigan.—According to F. R. Frye, petroleum engineer, Michigan Department of Conservation, 64 wells were completed in 1944 compared with 47 in 1943. The only discoveries were one each in Mecosta, Newaygo, and Ogemaw Counties, all undeveloped at the close of the year. Of the new wells, 13 were drilled in the Goodwell field of Newaygo County discovered in 1943, 13 in the Cranberry Lake field, 8 in the Woodville, and 8 in the West Evart field.

The West Evart, West Fork, and Ithaca fields were connected with gas-transmission systems during the year, and 8-inch lines were laid from the Woodville and Goodwell fields.

The Reed City gas field, purchased late in 1944, is to be used for gas underground storage.

Production in Michigan in 1944 increased 8½ percent over the 1943 output to 21,254 million cubic feet, an all-time high.

Mississippi.—Exploratory drilling in southern Mississippi yielded good results in 1944. The Gwinville field, a large reserve of natural gas and condensate with production from the Lower Eutaw and Upper Tuscaloosa formations, was discovered on July 26, 1944. Later development indicated reserves of gas and condensate in other sands of the Tuscaloosa.

H. M. Morse, supervisor, State Oil and Gas Board of Mississippi, reports that no new pipe lines were built in 1944, and no new regulations affecting natural-gas operations were made.

He reported natural-gas production in three fields as follows: Jackson gas field in Hinds and Rankin Counties, 851,736,000 cubic feet; the new Gwinville gas and distillate field in Jefferson Davis County, 55,801,000 cubic feet; and the new Bruinsburg gas field in Claiborne County, 9,574,000 cubic feet.

A cooperative oil and gas engineering committee was organized to collect and distribute to members technical and statistical information of a factual nature relating to the business of oil and gas production.

Missouri.—Frank C. Greene, geologist, Missouri Geological Survey, reports five small wells completed in Missouri during 1944, the same number as was reported in 1943. There were no new developments.

A pipe-line connection was completed between the Prairie Point pool in Platte County and the Fairfax industrial district in Kansas City, Kans.

Production is estimated by purchasing companies in the State at 152,547,000 cubic feet valued at \$22,430. Reported production in 1943 was 124,000,000 cubic feet valued at \$10,500 at the wells.

Montana.—J. R. Schwabrow, acting superintendent, Geological Survey, United States Department of the Interior, Casper, Wyo., has supplied information relative to natural-gas developments in Montana during 1944.

There were 81 gas wells drilled during the year, with a total open flow of 116,000 thousand cubic feet, compared with 51 completions in 1943 having a total open flow of 64,640 thousand cubic feet. A new field was discovered by a well in the northern part of Toole County which found gas in the top of the Madison limestone at 2,040 feet. Its open flow was estimated at 20 million cubic feet, with a shut-in pressure of 580 pounds. The only other discovery well, drilled to 2,331 feet in western Liberty County, also found gas in the top of the Madison limestone. Its open flow was 5 million cubic feet with shut-in pressure of 1,025 pounds. Neither of the new fields was put on production. The number of gas-well completions by fields follows: Bowdoin 52, Cedar Creek 17, Kevin-Sunburst 5, Cut Bank 3, Kicking Horse 2, Utopia 1, and Devon 1.

The output of the Cedar Creek, Cut Bank, and three of the smaller fields decreased slightly; all others registered gains. The Cut Bank field supplied 48 percent of the total marketed output in 1944 compared with 50 percent in 1943. Fields and the amount of gas marketed, in millions of cubic feet were: Cut Bank 14,926, Cedar Creek 5,867, Bowdoin 4,762, Kevin-Sunburst 2,047, Whitlash 1,066, Dry Creek 1,046, Bowes 506, Boxelder 456, Devon 344, Marias River 158, Haystack Butte 95, and Hardin 76.

Natural-gasoline plants in the Cut Bank and Dry Creek fields processed 12,278 million cubic feet of gas to produce 2,730 thousand gallons of natural gasoline in 1944 compared with 11,524 million cubic feet processed and 2,793 thousand gallons of gasoline produced in 1943. The plant in the Cut Bank field also produced 1,684 thousand gallons of propane-butane mixture and 200 thousand gallons of straight propane.

Gross production increased 4 percent from 31,597 million cubic feet in 1943 to 32,975 million in 1944. Repressuring and recycling accounted for 25 million, field use for 1,115 million, and losses for 486 million. Comparative figures for 1943 are 35 million, 1,038 million, and 199 million, respectively. Marketed production increased 3 percent over the 1943 total from 30,325 million cubic feet to 31,343 million.

New Mexico.—L. G. Snow, supervisor, Geological Survey, United States Department of the Interior, reports six gas completions in southeastern New Mexico in 1944 having a total daily initial production of 16.4 million cubic feet. Three of them discovered new production from Permian formations—two in Lea County at depths of 3,050 to 3,200 feet and 4,707 to 4,802 feet had initial productions of 2 million and 2.2 million cubic feet, respectively, and one in Eddy County at a depth of 703 to 710 feet had an initial production of 5.7 million cubic feet. The other three were in the upper zones of the Arrowhead and Lynn oil fields of Lea County and the Barber oil field of Eddy County. In 1943 there were two completions in Lea County and one in Eddy County.

In northwest New Mexico, six wells were completed in San Juan County compared with five in 1943. Three of the 1944 completions found gas in the Dakota sand in the Barker Creek gas field and three in the Pictured Cliffs sand in the Fulcher Basin gas field. Their total daily initial production was 22.3 million cubic feet. It was hoped that known gas reserves would be increased by a deep well begun in 1944 in the Barker Creek field. It is planned to test all formations down to granite at an estimated depth of about 10,000 feet. No information was given as to the progress of this test.

Plans are being made for enlarging the carbon-black plant operating in Lea County and for constructing two new plants. The shortage of carbon black essential in the manufacture of synthetic rubber has gained a high priority rating for the work. Two repressuring plants in Eddy County have installed additional cooling and absorption equipment and are now operated as natural-gasoline extraction plants. A 16-inch gas line was constructed during the year to carry residue gas from a gasoline plant in the Eunice field to a storage project in the Rhodes field in Lea County. A compression station was built near the plant.

Nine wells in the Bueyeros area, Harding County, produced 209.9 million cubic feet, and three wells in the Estancia area in Torrance County 15 million cubic feet of carbon dioxide gas. Both liquid and solid carbon dioxide is being made from the gas.

The reservoir pressures in Eddy County are no longer sufficient for direct connection with high-pressure gas lines, hence dry gas is now sold only for minor fuel and heating purposes. A more efficient use of gas from oil wells and of residue gas from gasoline plants probably will result from this condition. Sales of residue gas in 1944 were virtually the same as in 1943. The volume of gas returned to oil-producing formations increased about 10 percent over the 1943 record.

Natural-gas production in southeastern New Mexico totaled 127,223 million cubic feet in 1944. Of this amount 90,902 million was marketed or used in the field, 33,433 million was vented to the air, and 2,888 million was returned to formations. Natural-gasoline

plants processed 104,258 million cubic feet in 1944 compared with 98,859 million in 1943.

Gas sold for domestic and commercial uses in northwest New Mexico totaled 4,956 million cubic feet compared with 4,807 million in 1943. The amount vented or used in the field in that area during 1944 was not reported.

New York.—Efforts to find new supplies of natural gas in New York have yielded small returns in recent years.

C. A. Hartnagel, former State geologist, reports only one producing well among 17 wildcats drilled to the Oriskany sandstone in Allegany, Steuben, Chemung, and Schuyler Counties in 1944. It had an initial daily production of 9,000,000 cubic feet and is in Tuscarora Township, Steuben County, near the Woodhull gas field, formerly a highly productive area. Only 2 of 26 wells were successful in 1943.

The deepening of the discovery well in the Woodhull field, which was begun late in 1943, was continued to a depth of 8,625 feet in 1944 and reached the Ordovician formation, but only small flows of gas were encountered. It was originally a large producer at 3,957 feet in the Oriskany formation. A well begun in 1943 in Wyoming County reached a depth of 6,757 feet early in 1945 but showed only small flows of gas. Another well in the same area drilled to test the Medina sandstone was abandoned at 3,375 feet when only small production was found.

No new developments were reported in the old Trenton and Medina fields where a few wells are drilled from time to time as more natural gas is required.

New York produces less than one-third of the total State demand for natural gas. Large amounts of gas from other States are imported. Some of this gas is stored in depleted gas fields to build up a reserve for use in periods of peak demand.

No natural-gas production figures for New York were given, but it is probable that the decline that began in 1939 was continued in 1944.

North Dakota.—The only commercial gas found in North Dakota comes from Bowman County in the southwest corner of the State. Four wells were producing in 1944 compared with 7 in 1943. Gas is found in the Eagle sand or the Pierre shale in the Cedar Creek anticline.

The Montana-Dakota Utilities Co., which distributes the gas, has made a location for a well to be drilled in 1945. It is hoped that production may be increased by a number of new wells.

Total output in 1944 was 200,105,000 cubic feet—a 13-percent gain over the 1943 record. This information was supplied by Wilson M. Laird, State geologist, North Dakota Geological Survey.

Ohio.—The following information was furnished by Kenneth C. Cottingham, chief geologist, Ohio Fuel Gas Co.

There were no important discoveries in Ohio during 1944. Thirteen new gas pools—11 in the Clinton sand, 1 in the Oriskany, and 1 in the Berea—were opened. The largest pool comprised 1,000 acres and the average about 565 acres. Extensions were also made to some 15 known pools, and about 15 additional small pools proving close to 120 acres each were discovered. Approximately 1,000 acres were proved in the Clinton sand in Dover Township, Tuscarawas County; 700 in Huntington and 750 in LaGrange Townships, Lorain County;

and 650 in the Oriskany formation in Bath Township, Summit County.

Wells in all sands averaged smaller volumes than in 1943. The daily average production per new well in 1944 was 769,000 cubic feet compared with 913,000 in 1943. Clinton wells ranked first in average capacity in 1944, Oriskany second, and Newburg third. There were 9 more Clinton completions than in 1943, 36 more Berea, 3 more Oriskany, and 6 more Trenton. The number of completions in the Shallow sands declined 24, in Ohio shale 6, and in the Newburg 1.

The deepest Clinton test was in Harrison County. It was dry and was abandoned at 6,301 feet. The largest Clinton gas wells were 1 in Ashland County, 2,975 feet deep, and 1 in Lorain County, 2,449 feet deep. Each had an initial open flow of 12,000,000 cubic feet. The outstanding Oriskany well was in Columbiana County. Its open-flow capacity was 5,800,000 cubic feet at depths of 3,545 to 3,557 feet. Productive "sands" and number of wells drilled in each follows: Clinton 285, Berea 125, Shallow 33, Oriskany 20, Ohio shale 6, Trenton 6, and Newburg 3. In all, 478 gas wells were drilled, 23 more than in 1943. The number of dry holes was virtually the same as the previous year. Gas wells were drilled in 33 counties in 1944 compared with 29 in 1943. Stark County ranked first in the number of gas completions displacing Morgan County which dropped to sixth place. Muskingum County displaced Medina in second place. The highest-ranking counties and number of completions were: Stark 50; Muskingum 43; Lorain 35; Medina 34; Holmes 28; Noble 28; Morgan 26; Athens 25; Perry 23; and Monroe 21.

The first rotary well drilled in Ohio was begun in Belmont County in September 1944 and, in spite of difficult drilling, was completed by March 1945. It was bottomed at 7,455 feet in the Queenstown shale and abandoned.

Figures of natural-gas production in Ohio in 1944 are not yet available.

Oklahoma.—No gas reserves of major importance were discovered in Oklahoma during 1944. Twenty-three gas completions resulted from 373 wildcat wells compared with 23 from 310 wildcat wells in 1943. Garvin, Okfuskee, and Stephens Counties each had 3 gas discoveries, Lincoln 2, and Coal, Cotton, Hughes, Kay, LeFlore, Love, Okmulgee, Osage, Pawnee, Pittsburg, Pontotoc, and Seminole 1 each.

There were 82 gas wells drilled in the Hugoton field and 5 in the Cement. In all, about 212 gas wells were completed in the State during the year, an increase of 89 percent over the 112 drilled in 1943.

Elmer Capshaw, gas engineer, Oklahoma Corporation Commission, has supplied the following information. New discoveries fell far short of compensating for declines in reserves of old sands outside of the Hugoton field, and pipe-line companies were seeking new connections to meet increased demands for fuel gas. The Hugoton field was heavily drawn upon and will probably be more so in 1945. More gas was also piped from Kansas and Texas. In January 1944 gathering lines were connected with 43 wells in Texas County in the Hugoton field and took 1,047,125,000 cubic feet of gas. In the same period of 1945, 156 wells were connected from which 6,760,723,000 cubic feet were drawn.

Decreased local supplies will tend to increase the price of gas at the wells.

Production of casinghead gas has declined in recent years, and that of dry gas has increased. Figures for 1944 indicate 216,576 million cubic feet of dry gas taken by gathering lines—a 21-percent gain over the 1943 figure—and 125,184 million cubic feet of casinghead gas—a 9-percent decline from the 1943 figure. A total of 341,760 million cubic feet was reported for 1944—8 percent over the 316,938 million cubic feet reported for 1943.

Pennsylvania.—According to J. G. Montgomery, Jr., vice president, United Natural Gas Co., most of the drilling in Pennsylvania in 1944 continued to be in the shallow sands. Of 855 wells drilled in the shallow fields during the year, 625 (73 percent) produced gas. This compares with 770 drilled in 1943 of which 597 (75 percent) produced gas. Of the total, 454 were drilled in southwest Pennsylvania, 338 being productive, with a total daily open flow of 84,784,000 cubic feet. In the northern and central counties 287 of the 401 wells drilled were productive. Their total daily initial capacity was 39,900,000 cubic feet.

A test in Patton Township, Allegheny County, completed in December was the most important discovery of the year. Its daily initial open flow was 4,170,000 cubic feet, and rock pressure was 1,190 pounds per square inch. Production was in the Speechley sand. The probable extent of the pool was unknown at the end of the year. In McKean County there were 15 gas completions in a Haskill sand pool. Their daily initial volume averaged 200,000 cubic feet, and rock pressures were as high as 840 pounds per square inch. In Mercer County 6 of 10 wells drilled some distance northwest of known production in the shallow-sand area found gas in the Berea and Venango First sands at depths of 294 to 667 feet. Their daily initial open flows averaged 114,000 cubic feet.

Only three gas wells were completed in the deep-sand fields although exploratory drilling was unusually active. In Fayette County the Summit gas pool was extended by two wells with daily initial open flows of 690,000 and 1,250,000 cubic feet. Production was from the Oriskany and Onondaga formations. The only well drilled in the Potter-Tioga field was in a depleted Oriskany pool to be used for storage.

A test in Beaver Township, Crawford County, had a daily initial production of 190,000 cubic feet from the Oriskany sand and a rock pressure of 650 pounds per square inch. A second test in the same area failed to find production.

Oriskany tests in Beaver, McKean, Venango, and Warren Counties found salt water only. A well in Elk County encountered no sand at the Oriskany horizon and was being deepened. A test planned for the Medina sand in Crawford County was abandoned before reaching the formation because of mechanical difficulties.

Two wells drilled to the Trenton lime found salt water. One in Mercer County was abandoned at 711 feet, the other in Butler County at 1,241 feet. A small show of gas was found in the Ordovician lime and dolomite, but a large volume of salt water was encountered 44 feet below the Trenton horizon.

A test in Butler County that was abandoned at 10,096 feet sets a new record for depth in the Appalachian area. It is believed to be

the deepest hole ever drilled with cable tools. Several strings of tools were lost when they encountered high-pressure gas pockets, but in spite of difficulties the work was completed in 16 months. Indications are that a number of exploratory wells will be drilled in the deep formations during 1945.

Production from the shallow fields in Pennsylvania failed to meet peak-load demands in 1944, although maximum withdrawals were made. It is estimated that output was about the same as in 1943. Figures of Oriskany production are not available. The Potter-Tioga field is no longer an important source of gas. There is no record of the output of the Fayette County field.

South Dakota.—According to J. R. Schwabrow, assistant superintendent, Geological Survey, United States Department of the Interior, Casper, Wyo., in 1944, one small gas well was drilled in South Dakota near Pierre.

State production totaled 7,332 thousand cubic feet, a 10-percent increase over the 6,655 thousand reported in 1943. The gas is used for heating the State capitol and for domestic purposes in Pierre.

Texas.—The marketed production of the natural gas in Texas is estimated to have increased 10 percent in 1944 over 1943 to about 1,460 billion cubic feet as all types of use within and outside the State continued to expand. The capacity of several major gas pipeline systems was increased during the year, and the completion in November of the new 26-inch line from South Texas to West Virginia provided a new outlet for 200 million cubic feet per day.

The continued development of the Carthage gas field in Panola County proved a gas reserve of the first magnitude. By early 1945 the productive area covered about 300 square miles, and estimated reserves exceeded 10 trillion cubic feet of gas and an ultimate condensate recovery of at least 20 million barrels. There are four important productive zones in the field, all with relatively high pressures—the Hill zone 2,100 pounds, Upper Pettit 2,600, Lower Pettit 2,700, and Travis Peak, 2,400.

Drilling at Carthage in 1944 included about 20 wells, many of which were dually completed. The productive area was extended several miles outward from the vicinity of Carthage which is now near the center of the proved area. The limits of the field are not yet defined.

Large-capacity pipe lines are already located in and near the field, and an additional line is projected to run northeast to supplement the declining capacity of the old Monroe (La.) gas field. Three natural-gasoline plants to process the gas are under construction.

Preparations for a large gas-repressuring operation in the West Pampa oil pool, Gray County, were progressing at the end of 1944. A cooperative agreement among 26 companies, covering 950 oil wells on 11,500 productive acres, was executed to govern joint activities. The project is expected to increase oil recovery about 40 million barrels above current production methods.

According to the Oil and Gas Journal, gas-well completions in 1944 totaled 268 — a gain of 91 percent over 1943. Almost half of the completions were in the Gulf Coast district, where active development of condensate fields for cycling continued and drilling for gas was stimulated by the prospect of a large, new market through the 24-

inch line mentioned above. Seventeen gas discoveries were reported in the Coastal district, of which at least 7 were of the condensate type.

Gas development in the Panhandle accelerated in 1944 as indicated by 47 gas-well completions compared with 30 in 1943. Three gas discoveries were listed for the district.

In other Texas districts, gas completions were as follows: South 32 (including 6 discoveries), East 29 (5 discoveries), West 15 (2 discoveries), North and West Central 15, South Central 2.

Early in 1945 the Texas Railroad Commission appointed an engineering committee to make a field-by-field study of gas waste to guide formulation of conservation policy. A preliminary survey indicated that 60 percent of the gas wasted to the atmosphere was being produced from 52 fields.

Utah.—J. R. Schwabrow, acting superintendent, Geological Survey, United States Department of the Interior, Casper, Wyo., states that there were no new natural-gas developments in Utah during 1944.

Gross production from Clay Basin, the only commercial gas field in the State, totaled 6,223 million cubic feet—20 million was used in the field and 6,203 marketed. In 1943 gross production was 3,893 million cubic feet—18 million was used in the field, 10 million lost, and 3,865 marketed.

Carbon dioxide gas amounting to 166 million cubic feet was produced from the Farnum dome compared with 161 million in 1943. The gas is used in the manufacture of dry ice.

Virginia.—There were no drilling operations in Virginia in 1944, according to William M. McGill, assistant State geologist, Virginia Conservation Division.

The well in Lee County, which was reported as drilled to a depth of 3,252 feet and capped in 1943, was not used in 1944. It is expected that it will be deepened early in 1945.

Production in Virginia comes from six wells in the Early Grove field in Scott and Washington Counties. It is found in the Little Valley limestone (Maccrady formation) of Mississippian age. One well was shut down for several months during the year for recasing. This was the primary cause of a decrease in output from 84,000,000 cubic feet in 1943 to 57,340,000 in 1944.

West Virginia.—David B. Reger, consulting geologist, Morgantown, W. Va., has furnished information relative to natural-gas operations in West Virginia in 1944.

Leasing of wildcat acreage was unusually active during the year. Possibly 6,000,000 acres were under lease in the State. Of the 40 wildcats drilled 25 discovered gas. At least 4 new gas pools were located, and new pools or wide extensions of old pools were indicated. Approximately 34,000 acres were proved. Comparative figures for 1943 were 42 wildcats drilled, of which 19 were gas wells, and 39,000 acres proved.

In all, 577 gas wells were drilled, more than in any previous year since 1937 and 102 more than the 1943 record. The daily open flow of the new wells totaled 305,372,000 cubic feet and averaged 529,241 cubic feet per well. New wells in 1943 had 454,735,000 cubic feet of daily open-flow capacity and averaged 957,337 cubic feet per well. The 45-percent decline in the average production per well in 1944 is

attributable to the decreased number of Oriskany wells, which are usually large.

Added daily production of 12,327,000 cubic feet of gas was found by deepening 107 old wells. Fifty-seven old wells were deepened in 1943, adding 11,484,000 cubic feet to daily production.

The decline in drilling to the deep Oriskany sand that characterized 1943 was continued in 1944. Forty tests were drilled, of which 20 (19 in the Charleston field) had commercial gas compared with 105 in 1943, of which 80 (all in the Charleston field) had commercial gas. One well with heavy rock pressure, the deepest of the year, was completed at 8,036 feet in Tucker County. It may make gas available from the closed dome of the large Blackwater anticline. Tests in Boone, Hancock, Preston, Putnam, Raleigh, Wayne, and Wood Counties were unsuccessful.

Two of three wells drilled to the Newburg sand were productive. Both were in Wayne County; one extended the Butler producing area $1\frac{1}{2}$ miles.

In southern West Virginia extensions to known pools producing from the Big Lime were made in Kanawha, Lincoln, Putnam, Raleigh, Wayne, and Wyoming Counties, and new pools were opened in Logan and Nicholas Counties. Little drilling has been done in the Big Lime, but it is hoped that upon development it will add materially to the State production.

Kanawha and Lincoln Counties led in the number of gas completions in 1944. Jackson County, first in rank in 1943 with 61 completions, had only 14 in 1944. Counties of greatest activity in 1944 were: Kanawha 74, Lincoln 74, Boone 53, Wayne 45, Clay 37, Gilmer 36, Upshur 33, and Calhoun 31.

The practice of storing gas in pools near trunk lines and areas of heavy demand was continued in 1944. Texas gas was brought to the State for the first time when the Tennessee Gas & Transmission Co. began delivering 200,000,000 cubic feet a day at the end of October. Of this, 50,000,000 cubic feet were sent to Ohio and the remainder to Pennsylvania and New York to supplement the Appalachian production, which has proved inadequate to meet industrial war demands.

Natural-gas production in West Virginia is estimated at 200,000 million cubic feet in 1944, an 11-percent decline from the 223,787 million reported for 1943. There were 14,720 gas wells operated, 411 more than in 1943. The average daily production per well was 37,225 cubic feet in 1944, a decline of 15 percent from the 43,848 reported in 1943.

Wyoming.—Seven gas wells were drilled in Wyoming in 1944, two at South Baxter, and one each at Bell Springs, East Mahoney, Powder River, Garland, and Little Grass Creek. The completions in Bell Springs, Powder River, and Little Grass Creek discovered new gas pools in the deeper zones. They were tests that failed to find oil in the deep Tensleep or Madison formations and were plugged back to gas-producing sands. The East Mahoney well was also a deep hole that was plugged back. Deep tests in the Big Sand Draw, Golden Eagle, Little Buffalo Basin, and South Elk Basin areas also found gas that may later be used either commercially or in the development of the oil pools.

The Little Grass Creek and Powder River fields were added to production in 1944, making a total of 35 that produce gas commer-

cially. Areas having the largest marketed production were Baxter Basin, 9,453 million cubic feet; Big Sand Draw, 6,456 million; Salt Creek, 3,405 million; Garland, 3,159 million; and Lance Creek, 2,608 million. These figures represent 70 percent of the total marketed production. Garland, with an increase of 1,175 million cubic feet in output, displaced Little Buffalo Basin among the top-ranking fields.

Natural-gasoline plants processed 22,985 million cubic feet of gas in 1944 to produce 34,480 thousand gallons of gasoline, a 1-percent decrease in total gas treated and a 9-percent increase in gasoline produced compared with the 1943 figures.

The Lance Creek, Salt Creek, and Big Sand Draw areas continued to be the main sources of gas for processing and furnished 94 percent of the total compared with 96 percent in 1943. Normal butane and isobutane were also recovered at plants in the Salt Creek field and butane in the Lance Creek, Medicine Bow, and Rock River fields.

Gross production in Wyoming totaled 51,602 million cubic feet in 1944—6 percent over the 1943 record of 48,476 million cubic feet. Repressuring accounted for 12,243 million, field use for 1,348 million, and losses for 2,012 million. Comparable figures for 1943 are: Repressuring 13,992 million, field use 1,090 million, and losses 1,474 million. The 36-percent increase in losses in 1944 was partly due to a greater amount of sour gas produced with oil from the Tensleep sand at Elk Basin. Field use increased 24 percent. The same eight fields had repressuring operations as in 1943. Lance Creek with 375 million cubic feet less and Salt Creek with 1,648 million less gas returned to oil reservoirs were the primary cause of a 13-percent decrease from the 1943 record. In all other fields repressuring operations increased, except in the Lost Soldier field, where 214 million cubic feet less gas was injected.

Marketed production registered a 13-percent gain and totaled 35,999 million cubic feet in 1944 compared with 31,920 million in 1943.

The above information was taken from a report from J. R. Schwabrow, acting superintendent, Geological Survey, United States Department of the Interior.

CONSUMPTION

The year 1943 was a critical one for the natural-gas industry. Increased demands by war industries and by concentrated groups of domestic and commercial consumers near such industries, together with difficulties in procurement of manpower and materials, posed many problems for distributors. Shortages occurred in some areas, and restrictions were placed upon some industrial uses of gas during periods of peak load, but on the whole the natural-gas business met the demands made upon it for essential service.

Total consumption was 3,403,479 million cubic feet—12 percent over the 3,044,773 million reported in 1942. The expansion that predominated in domestic and commercial markets in 1942 shifted to the industrial classes in 1943. Domestic and commercial consumption increased 8 percent and industrial consumption 13 percent over 1942 compared with respective gains of 16 and 7 percent in 1942 over 1941.

Natural gas consumed in the United States, 1939-43

Year	Domestic and commercial consumption

¹ Includes consumers served with mixed gas.² Chapters on Cement in Minerals Yearbook.³ Federal Power Commission. Figures include gas other than natural, impossible to segregate; therefore shown separately from main table.

Texas, California, Louisiana, and Oklahoma maintained the same rank as in 1942 as the largest consuming States, with gains of 15, 13, 14 and 4 percent, respectively. These States possess a plentiful supply of gas which, reflected in low-average wellhead values except in California, stimulates industrial utilization. In Texas and Louisiana in 1943, industrial consumption (which includes large oil-field and carbon-black components) was 93 and 92 percent, respectively, of total State consumption. On a regional basis increases in consumption of natural gas in 1943 over 1942 were as follows: Southwest 14 percent, California 13 percent, Southeast 9, North Central 8, Northeastern 8, and Rocky Mountain 5.

The average value of natural gas at points of consumption was 22.3 cents in 1943 compared with 22.7 cents in 1942. Slight gains in the value of gas used for field purposes and for carbon-black manufacture failed to offset decreases in the average value of gas used for domestic, commercial, and miscellaneous industrial purposes.

Natural gas consumed in the United States, 1939-43, by States, in millions of cubic feet

State	1939	1940	1941	1942	1943

* Includes natural gas piped from Canada.

* Small amount of gas consumed in Tennessee included with Virginia; separate figures not available.

Treated for natural gasoline and other light products.—Natural gas processed at natural-gasoline and cycle plants increased 6 percent to 3,028,000 million cubic feet in 1943, from 2,864,400 million in 1942. The ratio to total consumption was 89 percent, the lowest since 1939 when 87 was recorded. Gas processed in Louisiana decreased 4 percent following a 29-percent increase in 1942. Decreases were also recorded in Michigan, New Mexico, Ohio, Oklahoma, and Wyoming. Texas, with an 11-percent gain, accounted for 50 percent of the total gas processed in the United States. Arkansas made the largest proportional gain—71 percent over the 1942 record; and California reported a small increase, the first since 1938. The average yield of natural gasoline, including cycle products, was 0.92 gallon per thousand cubic feet of gas processed compared with 0.95 gallon in 1942. The average yield of all light products remained unchanged from 1942 at 1.22 gallons per thousand cubic feet.

Natural gas treated at natural-gasoline and cycle plants in the United States, 1939-43, by States, in millions of cubic feet

State	1939	1940	1941	1942	1943

Ratio to total consumption	2,150,000 87	2,471,400 93	2,763,300 99	2,864,400 94	3,028,000 89

Domestic and commercial.—The use of gas for domestic and commercial purposes has grown steadily since 1938 and in 1943 gained 8 percent over the 1942 record.

Domestic consumption increased 6 percent from 498,537 million cubic feet valued at \$352,520,000 in 1942 to 529,444 million cubic feet valued at \$370,558,000 in 1943. California, Colorado, and Wyoming were the only States reporting decreases. Commercial consumption totaled 204,793 million cubic feet valued at \$87,648,000 in 1943, compared with 183,603 million cubic feet valued at \$80,189,000 in 1942—a 12-percent increase in volume. Gains were made in all States except Kansas, Minnesota, and Missouri. There were 10,353,870 domestic consumers in 1943, 219,100 over the 1942 figure. The apparent decline in the number of domestic consumers in New York was caused by the transfer of a large group of meters from mixed gas to manufactured gas. All other States except Georgia and Pennsylvania recorded increases. There were 811,090 commercial consumers in 1943, compared with 778,830 in 1942. Twelve States reported fewer commercial consumers in 1943.

Domestic consumers paid an average of 70 cents per thousand cubic feet in 1943, 0.7 cent less than in 1942. Commercial consumers paid 0.9 cent less, or 42.8 cents per thousand cubic feet.

Consumption per domestic consumer averaged 51,135 cubic feet for the year, compared with 49,191 in 1942.

Domestic and commercial consumption of natural gas in the United States in 1943, by States¹

¹ Includes natural gas used with manufactured gas.² Maryland includes District of Columbia and Virginia.³ Utah includes North Dakota and South Dakota.

Field.—Field use took 23 percent (780,986 million cubic feet) of the total consumption in 1943 compared with 24 percent (721,063 million cubic feet) in 1942. Decreases were recorded in Colorado, Kansas, Michigan, Missouri, New York, Oklahoma, and Pennsylvania. Fewer wells were drilled in 1943 than in 1942, although efforts to find new production were encouraged by the Government. Shortages of manpower and materials continued to retard drilling operations. The 8-percent increase in field consumption in 1943 is related to a 25-percent gain in the use of gas lift for recovering petroleum in a few States and to greater shrinkage at gasoline and cycle plants.

The value of gas used in the field was strengthened in 1943, but gains in volume in States having low average values kept the total average practically unchanged from the 1942 level.

Carbon-black manufacture.—Although carbon-black production in 1943 was 3 percent greater than in 1942, the industry required 6 percent less natural gas because the average yield of black increased. Rapid expansion in the production of high-yield furnace-type blacks has resulted in a gain in average yield from 1.47 pounds of carbon black per thousand cubic feet of gas burned in 1938 to 1.88 pounds in 1943. There were 315,562 million cubic feet burned in 1943 compared with 335,533 million in 1942. The gas was valued at \$4,624,000 in 1943—an increase of \$286,000 over the 1942 record.

Carbon-black producers paid an average of 1.5 cents per thousand cubic feet in 1943 and 1.3 cents in 1942. The average cost of gas at plants has increased in each year since 1938.

New pipe-line outlets that afford improved markets for gas have reduced the amount available for carbon-black operations in some areas. Two pipe lines are proposed that will bring cheap gas to plants operating below capacity in the Texas Panhandle, in order to increase the supply of carbon black to meet the urgent needs for synthetic-rubber compounding.

Petroleum refineries.—Natural gas used as fuel in petroleum refineries increased 21 percent over 1942 (from 201,670 million cubic feet in 1942 to 243,584 million in 1943). This represented 26 percent of the total refinery fuel requirements in terms of B. t. u. in 1943 compared with 24 percent in 1942, and 15 percent in 1939. Texas, California, Louisiana, and Oklahoma, in the order named, maintained the same rank as in 1942 and collectively used 91 percent of the total volume of gas. Texas requirements increased 17 percent over the 1942 record, California 34, Louisiana 16, and Oklahoma 30. Decreases were reported in Illinois, Kansas, New York, Pennsylvania, and West Virginia.

Electric public-utility power plants.—Electric public-utility power plants used 305,576 million cubic feet of gas in 1943—28 percent over the peak of 238,736 million recorded in 1942. A small percentage of manufactured gas is included in the figures as reported by the Federal Power Commission. Districts showing the greatest changes from the 1942 records are the East North Central, with a 47-percent decrease; the West South Central, with a 36-percent increase; and the Pacific with a 199-percent increase. The West North Central reported a small decline; all others showed gains. Texas had the largest consumption of any State—106,061 million cubic feet (41 percent over

the 1942 figure and 35 percent of the total consumed in 1943). Louisiana, with a 17-percent gain to 41,268 million cubic feet, ranked second, California third with 36,049 million cubic feet, and Oklahoma fourth with a 45-percent gain to 24,040 million cubic feet. Decreases were reported in 10 States.

Since 1933 the utilization of gas for generating electricity has increased 198 percent; the total production of electricity, 161 percent; and the production of electricity from all fuels, 190 percent.

Portland-cement plants.—Natural gas consumed at portland-cement plants in 1943 fell 20 percent to a level below that of 1941, offsetting the 19-percent gain in 1942.

A total of 51,748 million cubic feet was used in 1943 compared with 64,540 million in 1942. This decrease was due to a 27-percent decline in portland-cement output in 1943 from the 1942 record.

In 1944, cement plants used only 35,588 million cubic feet of natural gas, the smallest quantity since 1935, as cement production declined 32 percent below 1943.

Other industrial.—Gas used for "other" industrial purposes, including fuel at public-utility power plants, continued the expansion that began in 1939. Consumption in 1943 was 1,277,362 million cubic feet compared with 1,039,827 million in 1942—a 23-percent gain. Increases were recorded in most States having abundant gas supplies; small decreases were reported in a number of States, some of which were effected by limitations in gas supply. The largest gains were in Texas, California, Arkansas, and Louisiana.

The average value of gas used at petroleum refineries, portland-cement plants, and for "other" industrial uses was 16.7 cents per thousand cubic feet in 1943 compared with 17.1 cents in 1942. The total value was \$262,819,000 in 1943, a gain of \$39,286,000 over the 1942 record.

Mixed gas.—The quantity of natural gas used with manufactured in 1943 was 10 percent above the 1942 figure. Gas used for domestic purposes gained 8 percent, for commercial purposes 5 percent, and for industrial purposes 20 percent. The increase in volume of industrial gas—from 18 percent of the total in 1942 to over 19 percent in 1943—contributed to the decrease in average value from 83.0 cents per thousand cubic feet in 1942 to 79.1 cents in 1943. A decline of 13.7 cents has taken place since 1939.

Natural gas used with manufactured gas totaled 84,853 million cubic feet valued at \$67,090,000 in 1943 compared with 77,259,000 million valued at \$64,093,000 in 1942. Illinois, with a 12-percent gain over 1942 requirements, and New York, despite an 8-percent decrease, maintained their rank as the two largest consumers.

There were 2,489,100 domestic and 133,130 commercial consumers in 1943 compared with 2,514,460 domestic and 138,040 commercial consumers in 1942. Although Indiana, Ohio, and Pennsylvania reported small declines, the decrease in the total number of consumers resulted primarily from the transfer of a large number of meters in New York from the mixed to the manufactured classification.

Industrial consumption of natural gas in the United States in 1943, by States and uses

INTERSTATE SHIPMENTS AND EXPORTS

Interstate shipments and exports to Canada and Mexico totaled 990,457 million cubic feet in 1943—8 percent over the 1942 record. Exports to Canada were virtually the same as in 1942; those to Mexico increased 29 percent. Texas, which now ships gas to 19 States and to Mexico and has ranked first in the volume transported since 1933, gained 4 percent over 1942. Louisiana, with a 9-percent gain, ranked second and West Virginia third, with a 7-percent gain. Movements from Arkansas, Illinois, Mississippi, Montana, New York, Utah, and Virginia decreased, all are relatively small in volume. Increases were registered in all other exporting States. Kansas gained 31 percent, Kentucky 15 percent, and Oklahoma 9 percent.

Ohio consumed 4,280 million cubic feet of Texas gas in 1943 compared with 607 million in 1942. This gain was made possible by the delivery of gas, beginning in the fall of 1943, into the system of the East Ohio Gas Co. through a new connection with the Panhandle Eastern Pipe Line.

As an indication of the magnitude of interstate gas shipments relative to marketed production and consumption in the more important "exporting" States, the adjacent table is presented showing the balance of these items in 1921, 1935, and 1943.

More than half of the gas produced and marketed in West Virginia has been piped to other States for more than 2 decades, and the same is true of Kentucky for a shorter period. The large-scale movement of gas from Louisiana and Texas began in 1928-29 after the completion of major pipe lines to distant markets. It is interesting to observe that Texas consumed more natural gas than was produced and marketed within its borders until 1931, importing the deficiency from neighboring States.

¹ Includes exports to Canada and Mexico.**PIPE-LINE DEVELOPMENTS**

The need for new gas-transportation facilities was increased in 1943 and 1944 by demands from important war industries coupled with limitations on supplies of other fuels. Several pipe-line projects designed to furnish new sources of gas in strategic areas were approved by the Federal Power Commission, and in 1944 a total of 3,012 miles of natural-gas lines was laid. The largest of these was a 1,265-mile line of the Tennessee Gas & Transmission Co. from Corpus Christi, Tex., to Cornwell, W. Va., to supplement insufficient supplies

of gas in the Appalachian area. The first pipe was welded January 10, 1944, and gas was flowing by October 31—a record-breaking achievement. The line comprises 1,180 miles of 24-inch and 85 miles of 20-inch pipe. The Louisville Gas & Electric Co. and subsidiaries of the Columbia Gas & Electric Corp., the Consolidated Natural Gas Co., and the National Fuel Gas Co. have arranged for deliveries from the line. The new connections built were about 135 miles of 12½-inch pipe from Hastings, W. Va., to Pew, Pa.; 57 miles of 12-inch line from Franklin to Elwood City, in western Pennsylvania; 65 miles of 16-, 20-, and 12-inch line from Marshall County, W. Va., to Washington County, Pa.; 60 miles of 8- and 12-inch line from Louisville, Ky.; and other short loops and extensions.

In response to growing markets for gas in California, the Pacific Lighting Corp. and the Southern California Gas Co. added 95 miles of 10-, 12-, and 24-inch pipe to their transportation systems in 1944. The new lines connect the Rio Vista gas field to the San Francisco Bay region and adjacent coastal territory and the La Goleta field to Ventura. They do not reach new sources of gas but make new connections with production and storage areas.

The Kansas Nebraska Natural Gas Co. built 156 miles of 8-, 12- and 18-inch line across western Kansas from the Hugoton field.

The 26-inch line of the Cities Service Transmission & Chemical Co. from Guymon to Blackwell, Okla., was completed early in 1944.

The Phillips Petroleum Co. finished 60 miles of line to serve carbon-black plants in the Texas Panhandle to enable them to operate to capacity.

The United Gas Pipe Line Co. was issued certificates by the Federal Power Commission to build a series of lines tapping new fields in southern Louisiana to supplement their available reserves.

A number of pipe-line companies built new loops to main lines and installed additional compressor horsepower to increase the capacities of their systems to deliver gas for market.

The prospects for continued expansion in gas transportation seem favorable as a number of projects are under consideration for 1945. There have been several requests for permission to extend lines into Wisconsin and Minnesota. These have been denied by the Federal Power Commission but probably will be reconsidered. The American Light & Traction Co. is planning a line from the Hugoton field in Kansas to Milwaukee and Detroit. The Consolidated Gas Corp. is contemplating a 215-mile line from Stephens County, Kans., to Wichita. The Memphis Natural Gas Co. requested authority to build 100 miles of line parallel to its present transmission system from the Monroe field in Louisiana to Memphis, Tenn. The request was denied at first, but the case was reopened in the fall of 1944, and certificates to build were granted. The Pacific Lighting Corp. is considering a line from the great Hugoton-Panhandle area of Kansas, Oklahoma, and Texas to California. Several new companies have applied for permission to make connection with the Texas-West Virginia line with the purpose of opening consuming areas to natural-gas service for the first time.

GENERAL REVIEW

New records were set in virtually every branch of the domestic oil industry in 1944. The total demand for all oils rose to 1,879 million barrels—a gain of 207 million barrels or 12 percent. Domestic demand, including all deliveries to our armed forces at home and abroad, amounted to 1,670 million barrels, and exports and shipments to Territories were 209 million barrels.

The total demand for all oils during the 5-year period 1940–44 amounted to an annual average of 1,634 million barrels and was almost five times the average for the 5-year period 1914–18.

The outstanding change in the supply and demand for all oils in the United States in 1944 was the increase in crude-oil production to 4,584,000 barrels daily—a gain of 459,000 barrels daily compared with 1943 and a gain of 742,000 barrels daily or over 19 percent compared with 1941. A further increase is indicated in 1945, as production in the first quarter rose to 4,769,000 barrels daily.

The effect of the war on the domestic petroleum industry is shown by the changes in the major problems of supply and demand. The expansion in normal business combined with the growth in the production of war materials for domestic defense and export raised the total demand for oil products above all former records in 1941. Major readjustments in 1942 included a sharp decline in total gasoline demand and a gain in fuel-oil requirements that involved material readjustments in refinery operation and yields; a major decline in imports and a substantial gain in exports; and an acute transportation problem resulting from enemy submarine operations and the diversion of tankers from the Gulf to East coast route to war uses that resulted in a drastic curtailment of oil consumption in the Atlantic Coast

¹ Data for 1944 are preliminary; detailed statistics with final revisions will be released later.

States. Major accomplishments in 1943 included the progressive improvement in the overland transportation situation with the completion of new pipe lines and the expansion in the tank-car movements of crude oil and products to the Atlantic Coast district and the further conversion of the refining industry to produce enormous quantities of aviation gasoline and other special war products. The increase in total war requirements in 1944 so far offset the curtailment in civilian consumption that the problem of total oil supply became acute, and every effort was made to expand domestic production and to operate refineries to the limit of effective capacity.

Total demand for all oils in the United States, 1935-44

¹ Subject to revision.

The demand for all oils in 1945 probably will materially exceed the record levels of 1944. The culmination of the war in Europe resulted in a total demand in the first quarter of almost 502 million barrels or 5,575,000 barrels daily and exceeded demand in the same period of 1944 by about 11 percent. Although termination of the European phase of the war may reduce the total military requirements for gasoline substantially, the demand for fuel oils for naval and shipping use should continue at peak levels, and a substantial increase in civilian consumption in the United States and abroad may be expected if adequate supplies are available.

Any present estimate of the postwar demand for domestic oil is highly speculative until future policies are defined more clearly. The demand for motor fuel in the United States depends on the rate at which the supply of motor vehicles can be restored to normal. The domestic demand for heavy fuel oils is closely related to the index of total industrial activity. The position of the United States in the international oil market depends on its ability to maintain domestic crude production; on recovery of oil markets and restoration of production and refinery facilities in Europe; and on expansion of oil production in the Caribbean and Persian Gulf areas and restoration of the oil industry in the East Indies.

The principal changes in the supply of all oils in 1944 included a gain of 172 million barrels in the production of crude petroleum, an increase of 12 million barrels in the output of natural gasoline and cycle plants, a rise of 29 million barrels in total imports, and withdrawal of 6 million barrels from stocks. The record production of crude petroleum totaled 1,688 million barrels. The largest gain was 154 million barrels for Texas, and the production of that State rose from 39.5 percent of the national total in 1943 to 44.6 percent in 1944. California production increased almost 28 million barrels and Louisiana production about 6 million. The largest declines in production were 7 million barrels for Kansas and 5 million for Illinois. The increase in total imports of all oils represented a gain of 31 million barrels in crude imports and a decline of 2 million barrels for refined

products. The 6-million-barrels decline in the stocks of all oils represented a decrease of 22 million barrels in crude stocks and a gain of 16 million barrels in stocks of refined oils.

The problem of transportation to supply the increasing demand for oil in the Pacific war area resulted in a substantial increase in California production and further withdrawals from storage. Crude production rose from 284 million barrels in 1943 to a new record of 312 million barrels in 1944. There was a further decline of over 11 million barrels in the stocks of all oils compared with declines of 27 million barrels in 1943 and 12 million in 1942. Steps were taken to expand the production of crude oil from naval reserves and to move West Texas crude by tank car for refining in California.

With termination of the war in Europe, the problem of oil supply in the Pacific will assume major importance and involve a maximum use of available tankers for the transport of oil from Gulf Coast and Caribbean sources. Although the war demand for gasoline may have passed the peak the supply of fuel oils for naval and shipping uses will be of even greater importance.

The gain of 207 million barrels in the total demand for all oils in 1944 represented increases of 117 million barrels for motor fuel, 43 million for residual fuel oil, 20 million for distillate fuel oil, 3 million for kerosene, 1 million for lubricating oils, and 23 million for all other oils.

¹ Final figures.
² Comparable with 1942.

³ As reported to Bureau of Mines.
 Subject to revision.

⁴ U. S. Department of Commerce.
 For comparison with 1944.

The demand for motor fuel totaled 695 million barrels in 1941, declined to 624 million in 1942 and to 620 million in 1943, and rose to 737 million barrels in 1944. Data compiled by the Bureau of Public Roads indicate a decline of about 187 million barrels, or almost 30 percent, in the civilian consumption of motor fuel from 1941 to 1943. It was not until 1944 that increasing war requirements, particularly for aviation gasoline, caused total demand to exceed the peak of 1941 by 42 million barrels. The gain of 117 million barrels in total demand in 1944 compared with 1943 represented increases of 68 million barrels in domestic demand (including shipments to our armed forces abroad) and 49 million in exports. These figures primarily reflect larger military requirements at home and abroad, as due to rationing, civilian consumption showed little further change.

The total demand for residual fuel oil rose from 482 million barrels in 1943 to 525 million barrels in 1944. Compared with 1941, total demand has risen 127 million barrels. The major increase in demand has been for naval use, but railroad consumption has risen about 33 million barrels, and the gain in use to propel vessels is estimated at about 28 million barrels. A decline of about 7 million barrels in oil-company use has been offset by a rise in industry uses.

The total demand for distillate fuel oil rose from 233 million barrels in 1943 to 253 million in 1944. The 20-million-barrel gain resulted from an increase of 18 million barrels in exports and of 2 million barrels in domestic demand. The increase in total demand since 1941 has amounted to about 63 million barrels and has been due primarily to the increase in exports and in naval requirements. Consumption for heating uses declined about 11 million barrels, or 10 percent, but was offset by gains in railroad and industrial consumption.

The daily average demand for all oils in the United States was 5,133,000 barrels in 1944 compared with the prewar peak of 4,369,000 barrels daily in 1941—a gain of over 17 percent. Much of the normal seasonal fluctuation in demand has been eliminated by the steady increment in military requirements. The trend of demand in 1944 and early 1945 is reflected in the progressive changes in operations by quarters.

The total demand for all oils in the first quarter of 1944 amounted to an average of 5,019,000 barrels daily—a 21-percent gain over the corresponding period in 1943. Crude production averaged 4,411,000 barrels daily, and total crude runs to stills were 4,374,000 barrels daily. There was a reduction of almost 11 million barrels in the stocks of all oils during the quarter. The increased operations in the first quarter reflected preparations to meet the oil requirements for the major offensive in Europe.

The daily demand for all oils in the second quarter of 1944 averaged 5,085,000 barrels—a gain of about 1 percent compared with the first quarter but 11 percent more than in the second quarter of 1943. There was a substantial increase in crude production to 4,529,000 barrels daily and in total crude runs to 4,525,000 barrels daily. There was a minor increase in the stocks of all oils of less than 1 million barrels representing a decline of about 7 million barrels in crude stocks and a gain of almost 8 million in stocks of refined products.

FIGURE 1.—Supply and demand of all oils in the United States, 1918-44.

Exports of all oils rose from 36 million barrels in the first quarter to 61 million in the second quarter. The increase in production and runs to stills was supplemented by a gain in total imports from 20 million barrels in the first quarter to 26 million in the second quarter.

During the third quarter of 1944 there was a minor decline in the total demand for all oils to 5,066,000 barrels daily, but demand was 7 percent above that in the same period of 1943. There was a further substantial gain in crude production to a daily average of 4,669,000 barrels, and crude runs to stills rose to 4,641,000 barrels daily. Stocks of all oils increased by over 13 million barrels during the quarter, representing a decrease in crude stocks of over 6 million barrels and a gain of 20 million barrels in stocks of refined oils. Total exports rose to a peak of 63 million barrels. The further increase in supply was essential to meet the winter demand for fuel oils and the upward trend in war requirements.

In the fourth quarter of 1944 the total demand for all oils mounted to 5,360,000 barrels daily—a 6-percent gain compared with the third quarter and almost 11 percent larger than total demand in the last quarter of 1943. There was a moderate increase in crude production to 4,724,000 barrels daily and in total runs to stills to 4,662,000 barrels daily. Stocks of all oils declined about 9 million barrels—a decrease of 2 million in crude stocks and 7 million in refined stocks.

New records were set in the first quarter of 1945. The demand for all oils averaged 5,575,000 barrels daily—a gain of 215,000 barrels daily or 4 percent compared with the fourth quarter of 1944 and an 11-percent increase compared with the first quarter of 1944. Crude production rose to 4,769,000 barrels daily and total crude runs to 4,736,000 barrels daily. Stocks of all oils declined about 20 million barrels in the first quarter. The further gain in supply was essential to meet the military requirements for termination of the war in Europe and the increasing demand in the Pacific.

RESERVES

The American Petroleum Institute Committee on Petroleum Reserves estimated reserves of crude oil in the United States on January 1, 1945, at 20,453,231,000 barrels. These reserves include only crude oil and condensate in known and proved fields recoverable under existing economic and operating conditions. Additions to reserves during 1944 totaled 2,067,500,000 barrels and represented 511,308,000 barrels from new pools discovered during the year and 1,556,192,000 barrels due to upward revisions of reserve estimates for fields discovered before 1944. The increase in total reserves amounted to about 389 million barrels during 1944 after deduction of a record production that exceeded the prewar peak of 1941 by about 276 million barrels.

The largest gains in reserves were 170 million barrels for Mississippi, 89 million for Louisiana, 83 million for Wyoming, 61 million for Oklahoma, 50 million for Texas, and 44 million for Colorado. The greatest declines in reserves were 91 million barrels for New Mexico, 44 million for Kansas, and a total of 21 million in the Appalachian States—Pennsylvania, New York, and West Virginia.

Estimates of proved oil reserves in the United States on January 1, 1939-45, by States¹

¹ From reports of Committee on Petroleum Reserves, American Petroleum Institute, of the amount of crude oil that may be extracted by present methods from fields completely developed or sufficiently explored to permit reasonably accurate calculations. The change in reserves during any year represents total new discoveries, extensions, and revisions, minus production.

TRANSPORTATION

The two major pipe lines constructed with Government funds and operated by the War Emergency Pipelines, Inc., were a major factor in solving the internal transportation problem in 1944.

The 24-inch crude line extends 1,254 miles from Longview, Tex., via Norris City, Ill., to Philadelphia and New York. From the initial delivery at Norris City in February 1943 through April 1945 about 223 million barrels of crude oil were delivered—46 million barrels to Norris City, 101 million barrels to Philadelphia, and 46 million to the New York district. During the last 11 months of this period total deliveries averaged over 317,000 barrels daily.

The 20-inch products line extends 1,475 miles from Beaumont, Tex., to New Jersey. From the initial shipment from Beaumont in January 1944 through April 1945, 84 million barrels of refined products were delivered. The peak daily throughput was 240,000 barrels. The rated capacity for gasoline is 235,000 barrels daily and 190,000 barrels daily for domestic heating oils. During culmination of the war in Europe, the line was devoted primarily to moving products for military use abroad.

The operation of these pipe lines to capacity released tank cars for essential movements between other districts. The peak of the tank car movement into the Eastern States reached about 1,000,000 barrels

daily in July 1943 and declined to about 500,000 barrels daily by the end of 1944. A substantial movement of crude oil by tank car to California refineries was inaugurated late in 1944.

The extent of the disruption of the normal movements of oil is indicated by the proposed extension of Government transportation subsidies, amounting to \$215 million, for the fiscal year 1945-46. Of this total, \$150 million is to cover possible requirements to meet extra transportation costs of crude oil or products into the Atlantic States, \$20 million for movements from the Southern and Mountain States into the North Central States, and \$45 million to cover the extra cost of moving West Texas crude oil to California by tank car.

WORLD OIL SUPPLY

The world production of crude petroleum exceeded all previous records in 1944 and increased from 2,234 million barrels in 1943 to 2,617 million in 1944. Production in 1944 was 531 million barrels greater than in 1939. In comparison with 1939, the principal gains were 413 million barrels for the United States, 58 million for Russia, 51 million for Venezuela, and 6 million for Argentina. The chief declines in production were 20 million barrels for Rumania, 22 million for the Netherlands East Indies, and 7 million for Burma.

Before the war, the United States produced about 61 percent of the total world supply of crude petroleum and by 1943 was producing 68 percent of the total. The disturbance of normal transportation routes, the diversion of tankers to war uses, and the capture by the enemy of important sources of supply in Rumania and the Netherlands East Indies led to increasing reliance on supplies from the United States to meet war requirements in Europe. Reopening of the Mediterranean route and increasing war activity in the Pacific have led to stimulation of production and expansion of refinery facilities in the Persian Gulf area and in the Caribbean. With termination of the war in Europe, these sources of supply will assume even greater importance and may, in the postwar period, change the competitive sources of world oil supply.

Current estimates of world crude-oil reserves outside the United States indicate a minimum of about 31 billion barrels, which may be increased materially by further exploration. About half of this reserve is in the Middle East, including Iraq, Iran, Bahrein Island, Saudi-Arabia, Kuwait, and Qatar. Since local consumption in these areas is of minor importance, any future expansion in production would compete in major consuming markets. Refinery capacity has been expanded materially during the war, and an increasing volume of products as well as surplus crude oil may be available for export. Transportation would be facilitated by the large increase in the world tanker fleet during the war, the possible increase in the pipe-line capacity from Iraq to Mediterranean ports, or the proposal to construct a pipe line from the Persian Gulf area to some terminus on the Mediterranean.

The most significant changes in the Caribbean area relate to Venezuela. Reserve estimates have been revised upward, production has been recently increased far above the prewar level, and refinery

capacity in the Netherlands West Indies has been expanded. A substantial increase in crude production and export may be expected in Colombia, and facilities in Peru have been increased to refine most of the production compared with the export of about two-thirds of the crude output before the war.

From the supply side, the major questions in the postwar period relate to the future rate of production in the United States, the actual increase in productive capacity in Venezuela, and the potential increase in the production in the Middle East. Other important considerations are rehabilitation of production and refinery capacity in Rumania and the Netherlands East Indies and of refinery capacity in France.

It is not easy to predict the future trends in total world demand for oil. Germany and Japan were among the large consumers of oil before the war. In the United States and northern Europe it may take several years to restore the supply of motor vehicles to normal. The degree of industrial activity and the volume of world trade will affect the consumption of fuel oils for manufacturing and bunker uses. International credit arrangements will be an important factor in the purchase of oil by countries that have other sources of fuel available.

An Anglo-American oil pact was signed on August 8, 1944, to become effective when ratified by the two Governments concerned. A great deal of discussion as to the terms and objectives of such an agreement has resulted in the United States, but no official action was taken in 1944. The original pact provided for an international commission to estimate world requirements and to make recommendations to secure adequate supplies for consuming nations and an orderly development of new reserves and production.

The significance of this pact is due primarily to the fact that the major part of the surplus production and reserves of oil outside the United States are held by United States, British, and British-Dutch oil companies. The other principal interests concerned represent the Government holdings in Russia, Mexico, and Argentina, and substantial holdings by French companies in Rumania and the Middle East.

CRUDE PETROLEUM

SUPPLY AND DEMAND

The total demand for crude petroleum in 1944 amounted to 1,745 million barrels and exceeded all previous records. The demand for domestic crude petroleum rose from 1,501 million barrels in 1943 to 1,701 million in 1944—a gain of 200 million barrels or over 13 percent. The increase in total requirements combined with an improvement in the ocean-transportation situation resulted in larger imports of crude oil, and the foreign crude run to stills rose from the low point of 12 million barrels in 1943 to 43 million in 1944. Compared with 1943, the production of domestic crude petroleum increased 172 million barrels, imports of crude gained 31 million barrels, and total stocks of crude oil were reduced by over 22 million barrels compared with an increase of 6 million barrels in 1943. The principal changes in demand were an

increase of 236 million barrels in total runs to stills, a decline of 7 million barrels in crude exports, an increase of almost 5 million barrels in transfers of crude oil to fuel oils, and a decline of 2 million barrels in other crude fuel and losses.

Supply of and demand for crude petroleum in the United States, 1940-44

³ Inclusive of heavy crude in California.

PRODUCTION

General.—The record production of crude petroleum totaled 1,677,753,000 barrels in 1944—a gain of 172 million barrels or 10 percent compared with 1943. The largest gains in 1944 were 154 million barrels for Texas and 28 million barrels for California. The largest decline was 7 million barrels for Kansas.

Texas and California retained their positions as the two leading States, with 44.6 and 18.6 percent of the total national output. Louisiana ranked third in the list of producers with 7.7, Oklahoma fourth with 7.4, and Kansas fifth with 5.9 percent.

FIGURE 2.—Daily average production of crude petroleum, total number of wells completed, and average price per barrel of a selected grade of Oklahoma crude petroleum in the United States, 1935-44, by months

Production in the East Texas field totaled 134,674,000 barrels in 1944—a gain of about 6 million barrels compared with 1943. Production in the Wilmington field in California increased about 3 million barrels to 36,943,000 barrels in 1944 and rose in the Coalinga field by about 4 million barrels to 35,404,000 barrels.

² Bureau of Mines.

³ Revised figure.

Alabama.—The discovery of the Gilbertown field, Choctaw County, marked the first commercial oil production in Alabama. The discovery well was drilled to 5,380 feet in the Comanche formation and plugged back to 2,585 feet, where it flowed 30 barrels of oil per day from fractured Selma chalk. A second well 5 miles west of the discovery found 50 barrels of oil and 40 barrels of salt water in upper Eutaw sands below 2,800 feet. Subsequent development of production between these two wells indicates probable continuity of a single field. Nine producers and five dry holes were drilled in 1944, and total oil produced was 56,000 barrels.

Nineteen wildcat wells were drilled in Alabama in 1944, principally in southwestern counties.

Arkansas.—Production of crude petroleum increased from 27,600,000 barrels in 1943 to 29,418,000 in 1944—a 7-percent gain in contrast to a 4-percent expansion in 1943 over 1942. Substantially higher production in the Atlanta, Dorcheat-Macedonia, McKamie,

FIGURE 3.—Production of crude petroleum in the United States, 1943-44, by States.

Midway, and Stephens fields offset losses in several areas, resulting in a net gain for the State.

Three minor fields—Calhoun, Wilkes, and Salem Church—were discovered in 1944. The Calhoun field is in Columbia County, and the other two are in Union County. The new production came from the Smackover lime, and the six wells in these new areas produced up to 100 barrels of oil or distillate a day each, at varying depths down to 8,300 feet. All drilling sites in the new fields were located by the seismograph.

There were 215 wells drilled for oil or gas in Arkansas in 1944 compared with 243 in 1943; however, results were more satisfactory in 1944, as the relative proportion of dry holes declined.

California.—Production of petroleum increased 10 percent in 1944 to 311,793,000 barrels, exceeding the old record in 1929 by 19,259,000 barrels. The trend was strongly upward through the first 9 months of 1944, and after hesitation in the fourth quarter gains continued in early 1945 as demand increased with the scope of military operations in the Pacific theatre of war.

The output of San Joaquin Valley fields increased 11 percent to 147,494,000 barrels, equaling 47 percent of total production in 1944, as in 1943. Increased output was reported in a number of fields, led by Coalinga, which gained over 4 million barrels, and Elk Hills, which responded to an intensive campaign of development. By Public Law 344, passed by Congress June 17, 1944, the Secretary of the Navy was authorized to develop Naval Petroleum Reserve No. 1 at Elk Hills to produce 65,000 barrels per day. By the end of September, 19 strings of tools were operating, and wells were completed rapidly through the end of the year. By February 24, 1945, 169 wells had been drilled, and daily production of the field had risen from about 15,000 barrels to over 63,000 barrels. The objective of 65,000 barrels daily was reached in March 1945, somewhat sooner than was initially estimated. The only field in the valley to show a large decline was Ten Section, which produced 4,624 thousand barrels in 1944, or 1,934 thousand barrels less than in 1943.

Production in the Coastal district increased 23 percent over 1943 to 50,003 thousand barrels. The largest gains were in the Santa Maria Valley and Ventura Avenue fields, which together produced over half the district's additional oil.

The Los Angeles Basin output increased from 110,628 to 114,296 thousand barrels owing to 3,923 thousand barrels more production from Huntington Beach and 2,580 thousand barrels more from the Wilmington field than in 1943. Other fields in the district, many of which are in the decline stage, produced 2,835 thousand barrels less in 1944 than in 1943.

Drilling was at record levels, 41 percent above 1943, spurred by the prospect of growing demand for petroleum for an indefinite period. Completions totaled 2,043, of which 1,663 were oil wells. The drilling of 316 exploratory holes resulted in 62 successful oil wells. The fields of most active development and the number of oil wells completed in 1944 in each were as follows: South Belridge 199, Wilmington 144, Midway-Sunset 138, Elk Hills 103, and East Coalinga 94. The world's deepest well was drilled into lower Miocene formations in the Cole's Levee field to a depth of 16,246 feet in 1944 and abandoned as a dry hole early in 1945.

The discovery of 25 new oil-producing areas and 8 new pools in oil fields was reported in 1944, in addition to numerous extensions to old fields. About half of the discoveries were in Kern County. None of the new fields was reported to be of major importance.

Probably the largest proved additions to reserves were uncovered in new pays in the Buena Vista Hills field, Kern County, and San Miguelito, Ventura County. The opening of production from 2 sands in the Pliocene at Northwest Elk Hills, Kern County, may develop important reserves.

³ Includes Tupman.

⁴ Includes Buena Vista Hills.

Colorado.—A sharp gain in output of the Wilson Creek field lifted Colorado production 27 percent to 2,944,000 barrels in 1944, a new record slightly above the old high of 1927. Production at Wilson Creek increased 84 percent over 1943 to 1,401,000 barrels, and Rangely gained 33 percent to 379,000 barrels.

Oil-well completions numbered 22 compared with 11 in 1943. Completions, by active fields, were: Clark's Lake 5 oil wells, North McCallum 5, Wilson Creek 5, and Rangely 3.

Development at Rangely in 1944 established a major reserve from which a 10-inch pipe line is projected for construction in 1945. A deep test at Powder Wash, Moffat County, was completed late in 1944, proving production from five sands—two oil, two gas, and one gas-condensate—between 4,000 and 5,200 feet.

^a Subject to revision.

Florida.—The State's only producing well, in the Sunniland field, Collier County, produced 11,832 barrels of 19° A. P. I. gravity oil in 1944 compared with 4,037 in 1943. Six wells were drilled in 1944; however, all were abandoned. Depths of these dry holes ranged from 3,540 feet to 13,512 feet, and exploration was limited to Collier, Gulf, Leon, and Madison Counties. The formation tested was undetermined in Madison County; however, it was believed that the Comanche was penetrated in the other counties. Four wildcats were drilling at the end of 1944, and broader activities were expected in 1945.

Illinois.—Production of 75,822,000 barrels of oil in 1944 represented a 6-percent decline from 1943 and a 48-percent drop from the peak of 1940. Declines were reported from most fields, led by Loudon and Salem, the largest producers. The largest gain (2.1 million barrels) was reported from the Clay City field, where secondary recovery operations (water flood) are progressing. The relatively new Mount Erie field, Wayne County, increased its output from 229,000 barrels in 1943 to 1,322,000 barrels in 1944.

Oil-well completions were 1,196 compared with 1,046 in 1943. New oil wells in the most active fields were: Clay City 179, Albion 62, Phillipstown 60, Bible Grove 56, and Mount Carmel 44. Of 279 wells classified as wildcats, 22 discovered new oil pools. Exploration was directed chiefly toward the deeper parts of the Interior Coal Basin, and most of the discoveries were recorded there. The most important new pools indicated were: Boyd, Roaches North, and Divide West, in Jefferson County; and Calhoun, in Richland County. Except for the Lancaster East pool, Wabash County, which produced from the Pennsylvanian, all of the new pools obtain their oil from the Chester of Upper Mississippian and St. Genevieve beds of Lower Mississippian age.

The seismograph and subsurface geology are the two methods most used in Illinois exploration. However, the use of the seismograph declined about 50 percent in 1944. A few holes were drilled below the Mississippian but none was productive.

Indiana.—Production declined only slightly in 1944 to 5,118,000 barrels from 5,283,000 barrels in 1943. The Griffen pool produced 2,004,000 barrels in 1944 and 2,393,000 in 1943. The next largest producing fields in 1944 were New Harmony (396,000 barrels) and Mount Vernon (379,000 barrels). Owensville (and North) gained sharply to 248,000 barrels in 1944 because of new development. Two new fields which had very little output in 1943, Inman and Upton (Posey County), produced 151,000 and 107,000 barrels, respectively, in 1944.

Oil-well completions increased from 96 in 1943 to 144 in 1944. The most activity, with number of oil wells completed, was: North Owensville 23, Inman 22, Griffen 16, New Harmony South 14, and Upton 12.

Three new fields were discovered in 1944—the New Harmony South and Hovey in Posey County and Cato in Pike County. The St. Thomas pool, Knox County, was extended materially to the south.

Kansas.—Following 4 years of expansion, production declined from 105,697,000 barrels in 1943 to 99,857,000 in 1944. Minor reductions in output were the rule in all principal fields, more than 10 of which attained peaks in withdrawals in 1943. The three largest producing areas—Trapp-Sellens, Silica-Raymond, and Bemis-Walters—reported the greatest declines, followed by Peace Creek, which fell 44 percent. The largest increase in production was from the Carmi field, Pratt County, a 1943 discovery which produced over 2 million barrels in 1944.

Oil-well completions numbered 824 or 56 less than in 1943, although total completions were 102 greater in 1944 owing to greater exploratory effort and drilling in proved gas territory. The number of oil wells drilled in areas of greatest development in 1944 were: Kraft-Prusa 43, Zenith-Peace Creek 33, Trapp 31, Chitwood 25, Hall-Gurney and Morel 24 each.

Wildcatting results were generally discouraging, as no major new pools were indicated. The opening of large production from the Lansing-Kansas City limestone in the Adell pool, Sheridan County, was perhaps the most important development because it extended about 15 miles northwestward the area in which porous zones may be expected in this important producing formation. Ten producing wells and no dry holes were drilled in 1944, indicating one of the large reserves in northwestern Kansas. Three Simpson pools—Coates, Ludwick, and Shriver—were discovered in Pratt County, but none of these appears to have the prolific sand conditions of the nearby Chitwood field. Production from the Viola limestone was discovered in the Skinner field, Barber County.

Three discoveries were reported in Stafford County: The St. Johns and Richland pools producing from Arbuckle dolomite and McCandless producing from Simpson sand. Several new pools and extensions were developed in Rooks and Ellis Counties near recently discovered producing areas, and other scattered discoveries, apparently of minor potentialities, were made along the Barton arch district.

Kentucky.—Field activities reached a new level in 1944, with the result that several new pools were discovered, and production increased from 7,883,000 barrels in 1943 to a record of 9,621,000 in 1944. There were 993 drilling tests completed in 1944 compared with 656 in 1943. The proportion of dry holes dropped from 38 percent in 1943 to 31 percent in 1944, while producing oil wells increased from 37 percent of 1943 completions to 38 percent in 1944. Most of the exploratory work was confined to the western coal basin of the State, where about 700 test wells were completed in 1944 (216 in 1943) to prove 12 new pools. Initial production in the new areas ranged from 13 to about 125 barrels per day at depths of 1,026 to 2,710 feet. The East Clay pool, discovered in Webster County in August and producing from a Pennsylvanian formation, made the best initial showing in 1944.

Louisiana.—Production increased 5 percent over 1943 to a new record of 129,207,000 barrels, owing to continued gains in the Gulf district that have offset declines in the north for 2 years. Gains were reported from numerous Gulf fields, the largest being at Vinton, which also led the State in development. Other notable gains were at Bayou Sale, Delta Farms, Gibson, and Neale.

In Northern Louisiana production declined 12 percent to 24,014,000 barrels as smaller output was indicated from all leading fields. Haynesville declined almost 1.6 million barrels (29 percent) from its 1943 peak, and the output of Olla and Rodessa continued to shrink materially. A large repressuring project was initiated in 1945 to sustain production at Haynesville.

Oil-well completions in the Gulf district increased from 210 in 1943 to 310 in 1944 as development of known fields increased. Those with the largest number of new oil wells in 1944 were: Vinton 29, Neale 15, Delta Farms 15, and Pine Prairie 14. In the Northern district oil-well completions fell from 126 in 1943 to 119 in 1944, but the number of dry holes and gas wells increased. The most active fields were Holly (20 oil wells), Caddo (17), Holly Ridge (16), and Lake St. John (16).

In Southern Louisiana, 13 new fields were discovered as a result of 57 wildcat wells drilled. Most of the new fields were in a belt crossing the State 40 to 50 miles inland from the Gulf of Mexico. On the basis of early development, several of the new fields promise important reserves. The complex nature of most structures in the area, however, causes the projection of information ahead of the drill to have an inherently high factor of error.

New pay sands were found or important extensions made in many fields, including Bully Camp, Caillou Island, Pine Prairie, Batemen Lake, Bastian Bay, and Delta Farms.

In Northern Louisiana two oil fields and three condensate fields were discovered in 1944. The Delhi oil field, Richland Parish, in which oil was discovered from sand of probable Paluxy age at 3,273 to 3,291 feet, marks the first commercial oil production in north-eastern Louisiana. In DeSoto Parish, the Trenton oil field also produced from the Paluxy formation, at 2,728 to 2,732 feet. The three condensate fields were Benton in Bossier Parish, Sicily Island in Catahoula Parish, and Tremont in Lincoln Parish.

An important deep pay discovery was made in the Haynesville field, Claiborne Parish, when 44° gravity oil was produced from sands in the Cotton Valley formation below 8,800 feet.

Michigan.—Crude-oil production declined for a second consecutive year when the 1944 total of 18,490,000 barrels was 11 percent below the 1943 output of 20,768,000 barrels. Gains in the Adams (Arenac County), Ford (Mecosta County), and Kawkawlin (Bay County) fields were not sufficient to offset losses in the important Reed City (Osceola and Lake Counties) and six lesser areas. Production in the

Reed City field declined from a peak of 9,102,000 barrels in 1942 (42 percent of the State total) to 7,847,000 in 1943 (38 percent of the State total) and to 5,194,000 in 1944 (28 percent of the State total).

There were 655 wells completed in 1944 compared with 628 in 1943. Oil-well completions increased from 235 in 1943 to 239 in 1944, and dry holes abandoned were 357 in 1944 compared with 346 in 1943.

Development activities resulted in the discovery of nine new oil fields and in the extension of, or new pay zones for, several others. Six of the new fields—Coldwater (Isabella County), Belly Achers (Montcalm County), Bloomer (Montcalm County), Deep River (Arenac County), Pinconning (Bay County), and Essexville (Bay County)—are in the "Basin" of Central Michigan, and production is from the Dundee or Devonian formation. Coldwater, Deep River, and Essexville added appreciably to known reserves of the State. Production depths ranged from 2,660 to 3,698 feet. Three other new fields were located in the southwestern Michigan Traverse area—Hilliards, South Monterey, and Wayland—all in Allegan County. Producing depths for Allegan County varied from 1,578 to 1,801 feet, and the highest initial daily production was for the Hilliards field—300 barrels.

Test-core drilling declined from 376 permits in 1943 to 181 in 1944, although this method of locating favorable structural conditions remained the most popular. Some gravimeter and seismographic studies also were made, and the latter technique led to the discovery of the Pinconning field in Bay County, where the initial well—Koth No. 1—produced 115 barrels an hour from the Dundee formation at 2,950 feet.

Thirty-three wildcat wells were reported in 1944, and all penetrated to the Devonian formation or deeper. Four wells in southeastern Michigan reached pre-Cambrian granite, and another sunk on the eastern edge of the "Basin" ended in Cambrian sandstone.

¹ Data from Department of Conservation, Michigan.

Mississippi.—Production of crude petroleum has declined from a peak of 28,833,000 barrels in 1942 to 18,807,000 in 1943 and to 16,337,000 in 1944. Oil wells completed increased from 31 in 1943 to 78 in 1944, but reported dry holes declined from 84 in 1943 to 77 in 1944. One gas well was announced in 1944.

Although drilling activities increased greatly in 1944, the new production brought in did not offset the continued decline in the output of the important Tinsley field (Yazoo County), where 92 percent of the State's output originated in 1943 in contrast to only a 72-percent share in 1944. Expanding production in 1944 in the

Pickens field (Madison and Yazoo Counties), Heidelberg (Jasper County), Cranfield (Adams County), and Eucutta (Wayne County) helped to counteract the declining output of the Tinsley field. The latter two fields were discovered late in 1943, and each reached a production of approximately 500,000 barrels in 1944.

Four new oil fields were located in Mississippi in 1944. The most important, the Heidelberg, was discovered in January and produced about 1,400,000 barrels from 57 wells. The producing-sand zones of the field are known locally as Morrison, City Bank, Stanley, and Christmas. The Gwinville (Jefferson Davis County) and Mallalieu (Lincoln County) fields were announced in August, and the Baxterville (Lamar County) field followed in November. Bruinsburg (Claiborne County), a gas field, was also discovered in November; however, it is not believed to represent an important reserve.

The further exploration and new discoveries in Mississippi resulted in an increase in the total reserves credited to the State from 39 million barrels on January 1, 1944, to 209 million as of January 1, 1945, as indicated in the report of the Committee on Petroleum Reserves of the American Petroleum Institute.

Montana.—Output in Montana increased 9 percent over 1943 to a new record of 8,627,000 barrels. Withdrawals from Cut Bank and Kevin-Sunburst were moderately higher, but the major gain was at Elk Basin, which produced 682,000 barrels in 1944 compared with 243,000 barrels in 1943.

Drilling, both development and wildcat, increased markedly in 1944 as a number of major oil companies became active in the region, indicating aggressive expansion of production and refining operations. A total of 221 oil-well completions was reported, 73 more than in 1943. Wildcatting in particular was active in the second half of the year. Oil-well completions in important fields were: Cut Bank 101, Kevin-Sunburst 87, High Gravity 11, Elk Basin 10, and Gage 4.

Four oil discoveries were reported, of which the Clark's Fork and Dry Creek fields, Carbon County, appeared to have the most promise. They produced from the second Frontier sand and Morrison, respectively. Oil from the Sunburst sand was found in the Willshaw block, Toole County, and at Farmington, Teton County, from the Ellis-Madison.

With respect to reserves and productive capacity, the continued development of the north end of the Elk Basin field doubtless was most important.

Nebraska.—Production declined from 635,000 barrels in 1943 to 417,000 barrels in 1944, of which the Falls City pool produced about 285,000 and Barada and Dawson about 60,000 barrels each, from a total of 79 wells.

Sixteen wildcats were drilled in 1944 without finding commercial production. Six of these were in western counties—Hitchcock, Dundy, Red Willow, and Garden. Ten were drilled in five eastern counties.

New Mexico.—A 2-percent gain in 1944 raised production to a new record of 39,751,000 barrels. Among leading fields the greatest increases in production were reported by Monument, Hobbs, Maljamar, and Arrowhead. Loco Hills continued the decline that began in 1942. Production from fields in the northwestern part of the State gained 23,000 barrels over 1943 to 448,000 barrels.

Oil-well completions increased 101 over 1943 to 283, of which 14 were in northwestern fields. The Grayburg-Jackson area continued to be the most active, with 58 oil wells completed, followed by Square Lake with 47 and Maljamar with 28. Other active fields with oil wells completed were: Lovington South 14, Loco Hills 14, Rhodes 13, Red Lakes 12 and Arrowhead 12. In the Northwest district, Hospah had 8 oil completions, Rattlesnake 4, and Red Mountain 2.

Active exploration, particularly of deeper formations, resulted in the discovery of nine new fields, of which four appeared to be of major size. For the first time commercial production was obtained from horizons below the San Andres formation. The first discovery in these older rocks was in the Drinkard pool, Lea County, where a large well was completed in the Yeso (Clear Fork) formation below 6,375 feet in September. In November Ellenburger limestone production was obtained in the Dulbin area, Lea County, by a well which flowed 297

barrels of 50° gravity oil from a depth of 11,895 to 11,933 feet. The third Lea County deep discovery, the Skaggs field, was made when production was obtained in December from the Wolfcamp formation at 7,700 to 7,725 feet. The well drilled to pre-Cambrian rocks at 10,440 feet, having missed the Ellenburger limestone.

Discovery of the West Lovington field (Lea County), producing from 375 feet of broken pay in the San Andres formation resulted in the largest addition to proved reserves in 1944. Fourteen wells were completed before the end of the year.

The Vacuum field was extended 2 miles westward by a small well, completed in September.

¹ Oil and Gas Journal.

New York.—Production declined from 5,059,000 barrels in 1943 to 4,697,000 in 1944, the lowest level since 1936.

According to Oil Weekly, oil-well completions totaled 781 in 1943 and 788 in 1944, and water-input wells totaled 442 and 446, respectively. Efforts to develop new shallow production or to extend known producing areas met with little success.

Effective August 1, 1944, a subsidy of 75 cents per barrel was granted by the Office of Price Administration for all Pennsylvania-Grade crude oil.

¹ Subject to revision.

Ohio.—Production continued the decline that has been common to all the old eastern areas, amounting to 2,937,000 barrels in 1944 compared with 3,322,000 in 1943. All grades of oil shared in the decline, with Lima falling most (about 37 percent). Pennsylvania-Grade production declined from 1,719,000 barrels in 1943 to 1,525,000 in 1944.

According to Oil Weekly, oil-well completions numbered 210 in 1944 and 152 in 1943. The most active counties, with the number of

oil wells completed in each, were: Perry 40, Muskingum 16, Licking 14, Monroe 13, and Washington 12. Oil completions by principal producing formations were: Clinton 67, Berea 53, and Shallow sands 36. Development of the Berea was curtailed sharply after 1941, but Clinton-sand oil completions have remained above the 1940 level, chiefly because of active exploitation of the rich Clayton pool, Perry County.

Additions to oil reserves were limited to a few minor extensions to existing fields. Two outpost wells in Pike township, Coshocton County, may stimulate further drilling.

The subsidy payment to producers, granted by the Office of Price Administration effective August 1, 1944, was 75 cents a barrel for Pennsylvania-Grade oil and 35 cents for all other grades produced in Ohio. This extra income is expected to encourage operators to expand secondary recovery activity.

Oklahoma.—The long decline in production was reversed in 1944, when 124,616,000 barrels were reported compared with 123,152,000 barrels in 1943. The greatest addition of new oil was from West Edmond, which rapidly expanded into a major field, producing 7,752,000 barrels in 1944 compared with only 322,000 in 1943. Paul's Valley added over 2.2 million barrels to its output in 1944, and other notable gains were recorded at Cumberland, Cement, and the Glenn pool-Sapulpa area, where secondary recovery operations are becoming a large factor.

As in other recent years, the largest declines were in the Oklahoma City field and the Seminole district, which produced 4.0 million and 2.7 million barrels less, respectively, in 1944 than in 1943. Material declines elsewhere were in Osage County, Bristow-Slick, and Nowata County.

Oil-well completions increased from 543 in 1943 to 1,031 in 1944, reflecting 256 completions at West Edmond compared with 11 in 1943. Other active fields, with 1944 oil-well completions, were: Loco and West 55, Velma and North 51, Paul's Valley and East 50, Cumberland 27, Glenn 26, Cement 24. Wildcat drilling increased in 1944 and was most active in Garvin, Hughes, Lincoln, Stevens, and Carter Counties.

About 40 new pools were opened in 1944, several of which may develop into important producers, but the reserves added by expansion of the West Edmond field dwarfed other operations, so far as presently known potentialities are concerned. By the end of the year West Edmond covered over 14,000 acres proved for Hunton limestone production, and a few wells were producing from Bartlesville sand. Trade reports indicate that about 165,000,000 barrels of new oil were proved in this field in 1944.

An important group of deep fields was opened in McClain and Cleveland Counties on the west flank of the Nemaha granite ridge—Moore West and South, West Noble, and Washington. Production was obtained from the Bartlesville sand, Bromide, and Second Wilcox sand. Although several million barrels of oil are indicated, more wells will be required to determine the size of these fields. Their presence, however, has encouraged prospecting in the great Anadarko basin.

Farther south, in Garvin County, the East Paul's Valley field was discovered in April, production being from a Pennsylvanian sand at 2,960–2,984 feet. Thirty-two producing wells were drilled in 1944, and active development continued in 1945. The Hoover Northwest pool, also in Garvin County, was opened in May by a well that produced 120 barrels per day from a Pennsylvanian sand between 1,107 and 1,120 feet. Two additional sands, at about 1,400 and 1,960 feet, were proved for production. At the end of the year, 14 wells were producing. The seismograph was instrumental in finding both of these fields.

In T. 10 N, R. 7 E, Seminole County, Booch sand production was found at 3,429–3,441 feet to open the Cheyarha pool. Sixteen oil wells were drilled in 1944 in this pool, and three were drilling in January 1945.

¹ Oil and Gas Journal.

Several wildcats were drilled in the western part of the State, of which two found oil. In southwestern Washita County, a well drilled to 9,971 feet was plugged back and produced 307 barrels of oil from granite wash at 5,540 feet. In northern Kiowa County, a large well was completed in the Springer formation at 1,728 feet.

Pennsylvania.—Production of 14,118,000 barrels in 1944 was 10 percent below 1943 and 21 percent below the recent high recorded in 1942. Output of the Bradford field, which dominates Pennsylvania production, declined 11 percent to 12.1 million barrels.

Drilling for oil, related almost exclusively to secondary recovery projects, was notably higher than in 1943, doubtless influenced by the subsidy payment of 75 cents a barrel granted producers to counteract higher operating costs. According to Oil Weekly, 1,410 oil wells and 1,268 input wells were drilled in 1944, compared with 1,122 and 1,104 in 1943.

No new oil was discovered in 1944. Of 12 deep wildcats drilled to the Onondaga or below, one in Mercer township, Butler County, was sunk to 10,096 feet. It was bottomed in a salt-water-bearing sandstone below 520 feet of Lower Ordovician dolomite (probably Beekmantown) in which a show of gas was encountered.

Disappointing results were reported from the oil-mining shaft at Franklin. Three pairs of radial holes have been drilled, but apparently recovery of oil is not great in relation to development costs.

¹ Subject to revision.

Texas.—Production of 748,122,000 barrels was 153,779,000 barrels above the record of 1943 and equalled 44.6 percent of the United States total, compared with 39.5 percent in 1943. For the second successive year, higher output was reported from all districts as pressure upon the industry for a greater volume of production for war activities continued throughout the year. The greatest district gains were as follows: West Texas 61,786,000 barrels, Gulf Coast 60,996,000, East Texas 12,345,000, and South Texas 12,213,000. These districts, except the Gulf Coast, supplied the crude that the 24-inch war-emergency pipe line transported to refineries on the East Coast.

Drilling activity was 30 percent above the low level of 1943, and oil-well completions increased 49 percent to 3,526. All of the net increase was in the West Texas and Gulf districts, where active development in a number of large fields was carried on. East Texas had fewer new oil wells than in 1943, and the rest of the State only 21 more.

Many fields contributed to the 30-percent increase in Gulf Coast production to a new record of 261,124,000 barrels in 1944. The same

leading fields as in 1943 reported the largest individual gains and maintained their relative positions in the following order: Conroe, Hastings, Friendswood, Thompsons, and Anahuac. Important gains were scored by several of the newer fields that have been extensively developed during the past 2 years, particularly Stowell, Stratton, and Fig Ridge.

A marked increase in drilling resulted in 804 oil well completions compared with only 245 in 1943. The increased activity was directed chiefly toward development of existing fields, as indicated by the modest gain in the number of dry holes to 1,935 in 1944 from 1,908 in 1943. The following were the fields of greatest development in 1944, with the number of oil wells drilled in each: Seeligson 79, Willamar 53, Slick-Wilcox 30, Fig Ridge 29, and Stratton 27.

More than 60 new fields or pools were opened on the Gulf Coast in 1944, most of which were concentrated in the belt of counties from Brooks on the south to Colorado and Wharton on the north. In the upper Coast section the new fields were reported to be of minor size, the most important of which may be the Smith's Point field, Chambers County, in which four wells producing from the Frio formation were drilled before the year end. Discouragements in the form of dry holes followed several of the other discoveries.

In the lower Coast district, two oil fields were discovered along the Cretaceous fault-line trend in Guadalupe and Zavala Counties, and five oil fields were discovered in the Wilcox trend.

In the Jackson-Yegua trend, there were 8 oil discoveries, and a number of important additions were made to known fields. Of 12 oil fields opened along the Frio-Vicksburg trend, the Canales and Tijerina fields in Jim Wells County and the East Alta Mesa and Scott and Hopper fields, Brooks County, are reported to have major potentialities. Discoveries in the lower Rio Grande Valley appeared to be limited to gas reserves.

West Texas production continued to increase to a peak of 505,700 barrels daily in September 1944, reflecting the added carrying capacity of two new pipe lines that went into service early in the year and emergency tank-car movements of the crude northeastward and to the Pacific coast. The output from all major fields gained sharply, led by Gaines-Yoakum, which more than doubled its yield to 33,785,000 barrels. Other outstanding gains were reported by the Slaughter field, Ector County fields, and Pecos County.

Stimulated by important recent discoveries and the mounting withdrawals of oil, drilling increased sharply over 1943, and 1,323 oil wells were completed compared with 717 in 1943. Development was concentrated in the Slaughter field that had 372 oil-well completions. Other very active fields were Fullerton (114 oil wells completed), North Cowden (75), Wasson (58), and Fuhrman-Masco (58). All the above fields were among the leaders in development in 1943 also.

Exploratory drilling, at almost double the rate of 1943, resulted in 15 new fields, of which 10 produced from the Permian, 3 from Devonian, and 2 from the Ellenburger. Growing emphasis was placed upon testing the deep formations below the Permian. The first oil from rocks of Devonian age in the Permian Basin was found in August in the Crossett pool, Crane County, at a depth of 5,300 to 5,390 feet. Four wells were completed in this pool in 1944. Two other Devonian

discoveries, both considered important, followed. The first, also completed in August, was drilled $1\frac{1}{2}$ miles south of production in the Fullerton field, Andrews County. It flowed 3,744 barrels from Devonian below 8,260 feet. The TXL field, Ector County, was opened in December 1944 by a large well flowing from Devonian dolomite at 7,886 to 8,050 feet. Drilling early in 1945 indicates that this field contains a major oil reserve.

Ellenburger discoveries were made in Crane County, 5 miles north-east of the Sand Hills field (at 5,800 feet) and in Crockett County on the Todd structure (at 6,142 feet). Important extensions of Ellenburger production were developed in the Keystone and Wheeler fields, Winkler County.

The East Texas district produced 185,170,000 barrels of oil in 1944 (7 percent more than in 1943), of which 135,121,000 barrels were from the East Texas field. The outstanding gain in output was from the Van field, which produced 6,411,000 barrels in 1943 and 12,168,000 in 1944. This field is almost completely controlled by a single company and has been operated efficiently and conservatively for a number of years.

The number of oil-well completions in the East Texas district continued to decline to 124 in 1944 from 157 in 1943. No drilling was done in the East Texas field, and 476 wells were abandoned. The most active fields were Newhope, Franklin County, and Weiland, Hunt County, with 23 oil wells each, and Manziel, Wood County, with 18.

Nine oil fields were discovered in 1944, five of which produced from lower Glen Rose or Travis Peak horizons. The largest appear to be Winnsboro in Wood County, producing from two limestones of the Rodessa series, and Sand Flat in Smith County, producing from the Paluxy. The development of two new producing formations at Newhope, in the Glen Rose and Travis Peak formations, indicated substantial additional reserves.

Moderate gains in production were reported in North and Central Texas in 1944. Drilling increased about 18 percent and resulted in 850 oil wells. The Hildreth field, Montague County, with 66 new oil wells, was the most active in 1944, and important extensions of its productive area were made. The discovery of 50-odd fields or pools was indicated; none of them promised to be large. Discoveries or extensions were developed in the Cisco, Canyon, Strawn, Bend, Mississippian, and Ordovician series.

Panhandle production of 33,435,000 barrels in 1944 was little changed from 1943. No extensions or discoveries of oil production were reported, and only 12 wildcat wells were drilled. Oil-well completions increased from 148 in 1943 to 227 in 1944, of which 95 were in Gray County, 87 in Hutchinson, and 42 in Carson.

¹ Subject to revision.² Includes crude oil consumed on leases and net change in stocks held on leases for entire district.³ Joiner, Kilgore, Lathrop, and other pools in Cherokee, Gregg, Rusk, Smith, and Upshur Counties.⁴ Includes other fields in Falls, Freestone, Limestone, and Navarro Counties.⁵ Includes the fields in and between Wilbarger, Wichita, Clay, Montague, and Cooke Counties on the north and Runnels, Coleman, Brown, and Comanche Counties on the south.⁶ Includes crude oil consumed on leases and net change in stocks held on leases for East (exclusive of East Texas proper) Central, North, and South Texas.⁷ Carson, Gray, Hutchinson, Moore, and Wheeler Counties.⁸ Includes fields in Brooks, Duval, Hidalgo, Jim Hogg, Jim Wells, LaSalle, Live Oak, McMullen, Starr Webb, and Zapata Counties.⁹ Includes the part of Jordan pool in Crane County.

West Virginia.—Production in 1944 of 3,070,000 barrels compared with 3,349,000 barrels in 1943, a reduction of 8 percent.

According to David B. Reger, Morgantown, W. Va., 71 oil wells were drilled in 1944 with an average initial daily production per well of 8.6 barrels. The most active counties, with oil-well completions in each, were: Roane 11, Calhoun 8 (5 in Sycamore pool), Clay 6 (all in Reed Fork pool), Ritchie 5, and Wetzel 5.

No oil discoveries were made. Drilling for oil was limited to inside locations and two or three marginal operations of little consequence. The subsidy payment to producers of 75 cents a barrel, granted as of August 1, 1944, by the Office of Price Administration, had no apparent effect upon field activity.

Production of crude petroleum in West Virginia, 1940-44, by months

Wyoming.—Production declined 5 percent to 32,388,000 barrels in 1944. Reduced output was reported from most fields, particularly in the black-oil production of Oregon Basin and at Lost Soldier,

Lance Creek, and Grass Creek. As in 1943, the largest gain was at Elk Basin, which responded to further development of its great reserve of oil in the Tensleep sand and to improved transportation facilities. At Steamboat Butte, a 1943 discovery, output almost tripled to 601,000 barrels. Smaller increases were recorded at Frannie, Big Muddy, and Cole Creek.

Oil-well completions totaled 167 in 1944 and 102 in 1943. Major development was at Elk Basin, with 46 new wells, and Oregon Basin, with 33. Ten wells were drilled in the Byron field and 10 in the Garland field, whose known reserves were greatly increased.

Exploratory drilling resulted in 18 discoveries and several important extensions to known producing fields. The opening of production in the Embar lime and Tensleep sand at Big Sand Draw, Fremont County, revealed great potential reserves. Other important new reserves were found in the Tensleep sand at Gebo Dome, Hot Springs County; Little Buffalo Basin, Park County; Spindletop, Natrona County; and Steamboat Butte and Winkleman, Fremont County. At Garland Dome, a major extension of Tensleep production was made and lesser extensions at Fourbear and Pitchfork, Park County.

Sundance production was developed at Bailey, Carbon County, and Lakota sand oil was discovered at Crook's Gap and Steamboat Butte, Fremont County. Production from the Embar formation was opened at Big Sand Draw, Half Moon, and Kirby Creek; and Muddy sand oil at Golden Eagle, Mush Creek, and North Big Hollow.

The capacity to produce oil in Wyoming is evidently much above the ability of available transportation and refining facilities to process it economically for consumption.

[†] Includes crude oil consumed on leases and net change in stocks held on leases for entire State.

Other States.—Five wildcat wells were drilled in Atchison and Holt Counties, Mo., but no oil was discovered. Development of the Tarkio pool, Atchison County, discovered in early 1943, continued and production exceeded 1,000 barrels per month. Missouri's total production in 1944 was about 45,000 barrels.

In Tennessee, several major companies are reported to have leased large areas of the Cumberland Plateau district with the intent of exploring the possibilities of pre-Mississippian production. One Ordovician test was started in Cumberland County.

Virginia produced 2,200 barrels of oil in 1944 from two Trenton limestone wells in the Rose Hill field, Lee County.

Wildcat drilling or leasing were reported in Georgia (six dry holes), Maryland (one dry hole), North Carolina (one test drilling), South Carolina, Arizona (six dry holes), Iowa (two dry holes), Utah (one dry hole), North and South Dakota, Washington, and Oregon.

WELLS

The number of wells drilled in the United States in 1944, including oil and gas wells and dry holes, rose from 17,884 in 1943 to 23,106 in 1944. The increased number of wells drilled reflects the need for further exploration and the discovery of new reserves to meet the rapid rise in production to meet war requirements and to insure an adequate supply after the war.

Oil-well completions rose from 9,717 in 1943 to 13,029 in 1944; the number of gas wells completed increased from 1,897 in 1943 to 3,065 in 1944; and the number of dry holes was 6,270 in 1943 compared with 7,012 in 1944. The total number of wells drilled in the first 6 months of 1944 was 10,472 compared with 12,634 in the latter half of the year.

¹ Oil and Gas Journal east of California; American Petroleum Institute in California.

An active drilling campaign was continued in California, where the total wells drilled rose from 1,447 in 1943 to 2,034 in 1944. The number of oil-well completions increased from 1,150 in 1943 to 1,663 in 1944. The number of wells drilled in Kentucky rose from 656 in 1943 to 993 in 1944—an increase of 337. This drilling resulted in the completion of 374 oil wells in 1944 compared with 243 in 1943. Drilling was particularly active in Oklahoma, where the total number of wells drilled increased from 1,184 in 1943 to 1,890 in 1944, and the number of oil-well completions rose from 543 in 1943 to 1,031 in 1944. The total number of wells drilled in Texas increased from 4,421 in 1943 to 5,729 in 1944, and oil wells completed rose from 2,373 in 1943 to 3,526 in 1944. The drilling of 5,410 new wells in Pennsylvania, New York, Ohio, and West Virginia resulted in the completion of 2,681 oil wells and 1,882 gas wells.

STOCKS

Total stocks of crude petroleum amounted to 226,969,000 barrels on December 31, 1944, compared with 249,404,000 barrels on January 1, 1944. Stocks of foreign crude increased by 1.1 million barrels during the year, and stocks of domestic origin declined by 23.5 million barrels. The principal changes in stocks of domestic crude by States of origin were declines of 10.7 million barrels for all grades of California crude, 6.2 million barrels for Texas, and 4.5 million for Wyoming.

Total crude-oil stocks declined about 47 million barrels in the 4-year period from the end of 1940 to the end of 1944. The major decreases by States of origin were 33 million barrels for Oklahoma, 19 million barrels for California, 8 million barrels for Wyoming, and 7 million barrels for Illinois. The only large increase was 25 million barrels for Texas.

¹ Final figures.

² For comparison with succeeding years.

³ Includes equivalents for wax, coke, and asphalt in barrels.

Changes in the stocks of refined products indicate the adequacy of crude-oil supply. Total stocks of refined oils rose from about 229 million barrels at the end of 1943 to 246 million at the end of 1944—a gain of almost 17 million barrels during 1944 compared with a decline of 18 million barrels in 1943. This improvement in the stock situation resulted from improved transportation facilities to distribute both crude and products and to the upward trend in production of crude. The decline in refined stocks in 1943 primarily took place in California, whereas the increase in 1944 was all in areas east of California.

CONSUMPTION AND DISTRIBUTION

Runs to stills.—Total crude runs to stills amounted to 1,666 million barrels in 1944, a gain of 236 million barrels (16.5 percent) compared with 1943. Foreign crude runs increased to 43 million barrels, and runs of domestic crude rose to a new record of 1,623 million barrels.

The principal changes in refinery operations, by districts, in 1944 were gains of 74 million barrels in crude runs in the Texas Gulf Coast, 63 million in the East Coast, 31 million in California, 27 million in the Louisiana Gulf, and 14 million in the Indiana-Illinois district. New records for crude runs were established in every district except the Appalachian and Arkansas-Louisiana Inland.

The major part of the increase in total crude runs resulted from a greater utilization of existing refinery capacity. The ratio of runs to the total capacity of operating refineries was about 93 percent in 1944 compared with about 85 percent in 1943.

Distribution.—The total demand for domestic crude petroleum rose from 1,501 million barrels in 1943 to another new record of 1,701 million barrels in 1944—a gain of over 200 million barrels or more than 13 percent. The increased demand was met by a gain of 172 million barrels in crude production and a withdrawal of over 23 million barrels from stocks of domestic crude oil compared with an increase of about 5 million barrels in such stocks in 1943. The supply of domestic crude petroleum was supplemented by an increase in the imports of foreign crude oil from 14 million barrels in 1943 to 45 million in 1944. Imports of refined oils decreased about 2 million barrels, and total stocks of refined oils showed a gain of almost 17 million barrels in 1944 compared with a decline of 18 million barrels in 1943.

Receipts of domestic and foreign crude petroleum at United States refineries totaled 1,436 million barrels in 1943 and 1,669 million in 1944. In 1944 receipts of foreign crude petroleum were about 45 million barrels or 2.7 percent of the total; interstate receipts of domestic crude were 634 million barrels or 38.0 percent of the total; and intra-state receipts were 989 million barrels or 59.3 percent of the total.

Refinery receipts of crude in 1944, by methods of transportation, indicated that 83.3 percent of the total was delivered by pipe lines compared with 82.1 percent in 1943; that 6.8 percent was delivered by tank car and truck compared with 10.7 percent in 1943; and that 9.9 percent was delivered by boat compared with 7.2 percent in 1943. These figures indicate an improvement in the supply of tankers that permitted larger imports of foreign crude oil and diversion of tank cars to the movement of refined products, with the relative gain in pipe-line and boat movements.

The principal changes in the market demand for crude petroleum by States of origin (computed from production and changes in crude stocks by origin) in 1944 compared with 1943 were increases of about 171 million barrels for Texas, 34 million for California, 9 million for Louisiana, 3 million for New Mexico, 2 million for Arkansas, and 2 million for Kentucky. The largest decreases in crude demand were 8 million barrels for Kansas, 5 million for Oklahoma, 3 million for Mississippi, 2 million for Michigan, and 2 million for Pennsylvania. Twelve States had a market demand exceeding 10 million barrels a year in 1944 and contributed about 98 percent of the total supply.

¹ Subject to revision.

The most notable change in crude supply was the increase in the demand for Texas crude from 583 million barrels in 1943 to 754 million in 1944—a gain of 29 percent. The relative contribution of Texas rose from 38 percent of total national demand in 1943 to 44 percent in 1944—a gain due to the ability to expand production and the improvement in internal transportation resulting from the operation of the 24-inch crude line and to the 20-inch products line from Texas to Illinois and to the East Coast States. The record production of 748 million barrels was supplemented by a withdrawal of 6 million barrels from stocks of Texas origin. Deliveries to refineries in Texas rose from 344 million to 424 million in 1944, and deliveries to refineries in other States increased from 226 million barrels in 1943 to 317 million in 1944. Deliveries to the East Coast district showed a gain of 47 million barrels and to the Illinois-Indiana district of 26 million compared with 1943.

California ranks second as a source of crude supply in the United States and furnished 19 percent of the total supply in both 1943 and 1944. The demand for California crude amounted to over 322 million barrels in 1944—a gain of 34 million barrels or 12 percent. The growing demand for oil to supply war operations in the Pacific and the increasing requirements for industrial and railroad fuels in the Pacific Coast area made it essential to increase production. Arrangements were made to produce a substantial amount of crude from the naval reserves in the Elk Hills district. Tank-car shipments of West Texas crude to California were inaugurated at the end of 1944 to utilize surplus refinery capacity. The record production of 312 million barrels was supplemented by a withdrawal of almost 11 million barrels from crude stocks of California origin. The increase in crude-oil supplies resulted in only a minor change in the stocks of refined oils compared with a decrease of 23 million barrels in 1943. Intrastate deliveries of crude to refineries amounted to 294 million barrels in 1944, 23 million barrels were transferred for direct use as fuel oil, and 5 million barrels were exported.

Louisiana was the third-largest source of domestic crude oil supply in 1944, furnishing almost 8 percent of the total. Demand rose from 121 million barrels in 1943 to 130 million in 1944. Production amounted to 129 million barrels, and about 1 million barrels were withdrawn from storage. Intrastate deliveries showed a substantial gain, but deliveries to the East Coast declined by about 3 million barrels.

The demand for Oklahoma crude continued to decline. Although production rose from 123 million barrels in 1943 to almost 125 million in 1944, withdrawals from storage were less than 1 million barrels in 1944 compared with a withdrawal of 7 million barrels in 1943. Deliveries of crude to refineries in Oklahoma increased from 48 million barrels in 1943 to 52 million in 1944, while interstate deliveries declined from 85 million barrels to 77 million.

1 Missouri (36), Tennessee (10), and Virginia (2).

2 Subject to revision.

3 Alabama (33), Missouri (34), Tennessee (10), Virginia (2).

The demand for Kansas crude rose rapidly from 61 million barrels in 1939 to 106 million in 1943 but fell to 98 million in 1944. The decline was due primarily to the decrease in production, as stocks increased slightly in both 1943 and 1944. As deliveries of 44 million barrels to refineries in Kansas have shown virtually no change during the past 3 years, the decline has been in interstate shipments. Deliveries to refineries in Illinois and Indiana declined from 44 million barrels in 1943 to about 40 million in 1944, and the emergency shipments to the Atlantic Coast in 1942 and 1943 ceased in 1944.

The demand for Illinois crude reached a peak of 145 million barrels in 1940 and then declined rapidly to 78 million in 1943, with a further small decline to 77 million barrels in 1944. There was no change in intrastate deliveries, amounting to 26 million barrels in 1944, or in shipments of about 15 million barrels to the Appalachian district. Deliveries to the Atlantic Coast were almost eliminated in 1944.

The demand for New Mexico crude increased from 38 million barrels in 1943 to 40 million in 1944. Deliveries to refineries in Texas rose from 25 million to 28 million barrels. Delivery of 5 million barrels to Illinois refineries in 1944 was over 2 million barrels less than in 1943.

There was virtually no change in the demand for Wyoming crude, which amounted to 37 million barrels in 1944. Production declined from 34 million barrels in 1943 to 32 million in 1944, but withdrawals from stocks of Wyoming origin were 2 million barrels greater than in 1943. Intrastate deliveries to refineries rose to over 17 million barrels, but interstate deliveries to Illinois, Indiana, Kansas, and Missouri declined over 3 million barrels.

The demand for Arkansas crude rose from 27 million barrels in 1943 to 29 million in 1944 and was due primarily to a corresponding increase in production. Deliveries to refineries in Arkansas totaled 14 million barrels.

The production of crude petroleum in Michigan declined about 2 million barrels and there was a corresponding reduction in demand that amounted to less than 19 million barrels in 1944. Intrastate deliveries of 17 million barrels were the same as in 1943, but shipments to western Ohio declined from 4 million barrels in 1943 to 2 million in 1944.

The demand for crude of Mississippi origin reached a peak of 30 million barrels in 1942, declined to 20 million in 1943, and to 16 million barrels in 1944. Deliveries to East Coast States have declined rapidly, and the chief markets in 1944 were in Kentucky, Ohio, and Illinois.

The production of crude oil declined in all the Appalachian States in 1944. Production in Pennsylvania fell from almost 16 million barrels in 1943 to about 14 million in 1944. The combined demand for Pennsylvania, New York, and West Virginia crude amounted to about 25 million barrels in 1943 and 22 million in 1944. Shipments from these States to New Jersey were about 4 million barrels in 1943 and 1944, and the remainder of the crude was refined in the Appalachian district.

The production and demand for Kentucky crude increased from about 8 million barrels in 1943 to almost 10 million in 1944. About half of the total is refined within the State.

PRICES AND VALUE

The most important change in the value of crude oil at the well in 1944 resulted from the stripper-well subsidy plan effective August

FIGURE 5.—Posted prices of selected grades of crude petroleum in the United States, 1935-44, by months.

1, 1944. Under this plan Federal payments of 35 cents a barrel were authorized for fields with average production of less than 5 barrels daily per well; of 25 cents per barrel for fields averaging 5 barrels and less than 7 barrels daily per well; and of 20 cents per barrel for fields averaging 7 barrels and less than 9 barrels daily per well. A number of other stripper pools have been granted similar subsidies because of high production costs. A payment of 75 cents per barrel for all Pennsylvania-Grade oil produced in Pennsylvania, New York, West Virginia, and Ohio also became effective at the same time.

These payments are made to the producer, and the purchaser is reimbursed by the Government. They are supplemental to posted prices. In view of this situation, the stripper-well premiums are included in the Bureau of Mines figures for average value at the well.

Complete data on such payments are not yet available by months for 1944. The amount of the subsidy payments is estimated at about \$5 million per month and, if spread over the entire national output, would raise the average value of crude oil by approximately 3 cents per barrel for a full year's production. The effect in 1944 would be roughly proportionate to the 5 months operation of the plan.

The preliminary estimate of the average value of crude oil at the well in 1944 is \$1.21 per barrel, including Federal premium payments, compared with an average value of \$1.20 in 1943. The average value per barrel in some States where a variety of different grades of oil is produced may show little change if the increased output has been in the lower-value crudes.

REFINED PRODUCTS

GENERAL REVIEW

The most significant changes in the demand for refined products in 1944 were the expansion in the demand for aviation gasoline and the increase in fuel-oil consumption for naval and shipping uses. The civilian consumption of motor fuel was reduced to essential levels by progressive rationing in 1942 and 1943. The principal reduction in the consumption of oil for heating purposes was attained in 1943, although a small further decline is indicated in 1944. The major increase in the consumption of fuel oil by railroads took place in 1942 and 1943 and showed no material increase in 1944.

New records were established in virtually every branch of the refining industry in 1944, with a major increase in the supply of crude oil due to a gain of 172 million barrels in domestic production, an increase of 31 million barrels in crude imports, and a withdrawal of 22 million barrels from crude stocks.

Crude runs to stills rose from 1,430 million barrels in 1943 to 1,666 million in 1944—a gain of 236 million barrels. On a daily average basis, these runs amounted to 3,917,000 barrels daily in 1943 and 4,551,000 barrels daily in 1944—a gain of over 16 percent.

¹ Subject to revision.² New basis—to compare with following year.³ Negative quantity; represents net excess of unfinished rerun over unfinished produced.⁴ Not available.

New records were set in the total demand for all refined products in 1944 except for petroleum coke and road oil. The total demand for motor fuel amounted to 737 million barrels, for residual fuel oil to 525 million barrels, and for distillate fuel oil to 253 million barrels. These three products combined represented 81 percent of the total demand for all oils.

Exports of refined products totaled 175 million barrels in 1944 compared with 107 million in 1943. Exports of motor fuel rose from 52 million barrels in 1943 to 101 million in 1944; exports of distillate fuel oil increased from 25 million barrels in 1943 to 43 million in 1944; and exports of residual fuel oil declined from 15 million barrels in 1943 to 14 million in 1944. These three products represented 90 percent of the total exports of refined products in 1944.

The domestic demand for all oils, including military consumption at home and all shipments to our armed forces abroad, amounted to 1,670 million barrels in 1944 compared with 1,521 million in 1943. The domestic demand for motor fuel rose from 568 million barrels in 1943 to 637 million in 1944 but was 31 million barrels less than the peak demand in 1941; the domestic demand for residual fuel oil increased from 467 million barrels in 1943 to 511 million in 1944; and the domestic demand for distillate fuel oil showed a small gain from 208 million barrels in 1943 to 210 million in 1944. The three products together represented 81 percent of the total domestic demand.

Total imports of refined products were reduced to about 24 million barrels in 1942, owing to a scarcity of tankers and to enemy submarine attacks, but increased to 50 million barrels in 1943 and showed a small decline to 48 million barrels in 1944. Residual fuel oil has been the principal refined import and has been used primarily for bunkering vessels engaged in the foreign trade. Imports of residual fuel oil amounted to 37 million barrels in 1941, fell to 18 million in 1942, and rose to 27 million in 1943 and 37 million in 1944. Imports of distillate fuel oil rank second in importance and rose from 4 million barrels in 1942 to 15 million in 1943 and declined to 7 million barrels in 1944.

Changes in the amount of crude oil refined and in the demand for the major products have been reflected in the variations in refinery yields. The yield of gasoline declined to a low of 37.1 percent in 1943, when civilian consumption was being progressively reduced and before the full effect of war demands was felt. The expansion in production to meet military requirements in 1944 resulted from the large increase in crude runs, combined with the higher yield of 39.4 percent. The yield of residual fuel oil rose from 24.3 percent in 1941 to a peak of 29.2 percent in 1943 and declined to 27.7 percent in 1944. The yield of distillate fuel oil was 13.4 percent in 1941, 14.7 percent in 1942, 14.8 percent in 1943, and 14.4 percent in 1944. The higher relative yields of fuel oils reflected the expansion in naval and transportation requirements.

The completion of most of the new major pipe lines during 1943 or early in 1944 resulted in better distribution of crude oil to refineries and of products for internal consumption. As pipe-line deliveries to the East Coast increased progressively, tank cars were released for essential movements in other districts.

Readjustments in transportation and changes in the relative demand for products have resulted in substantial changes in the stocks of refined products. Total stocks of refined oils have declined

from 294 million barrels at the end of 1941 to 246 million barrels at the end of 1944. The reduction of such stocks by 47 million barrels in 1942 was due primarily to heavy withdrawals to supply demand in the East Coast district. The total reduction of 18 million barrels in 1943 represented a decline of 23 million barrels in California and a gain of 5 million in districts east of California. The increase of almost 17 million barrels in total refined stocks in 1944 occurred in areas east of California. The major change in refined stocks since the end of 1941 has been the cumulative decline of 32 million barrels in California and has been primarily a liquidation of stocks of residual fuel oil. In view of the growing demand for refined products and the readjustments in transportation and distribution, stocks of refined oils have generally been reduced to essential minimums. The stock figures used represent products in the custody of the oil companies at refineries and bulk terminals but do not include stocks in the custody of our armed forces either at home or abroad.

FIGURE 6.—Yields of principal products from crude oil run to stills in the United States, 1936-44, by months.

4 Subject to revision.

There were some reductions in the representative prices of refined products in 1944. The price of Regular-Grade gasoline at Oklahoma refineries was 6.00 cents per gallon for the first 7 months of the year but declined to 5.90 cents in August and to 5.875 cents per gallon for the remainder of the year. The tank-wagon price of kerosine at Chicago remained constant in 1944 at 10.60 cents per gallon. The price of bright stock at Oklahoma refineries, at 22.75 cents per gallon, showed no change during the year. The price of Bunker "C" fuel oil at New York was \$1.86 per barrel for the first 7 months of 1944 and dropped to \$1.77 per barrel for the last five months of the year.

FIGURE 7.—Prices of Bunker "C" oil at New York, bright stock at Oklahoma refineries, tank-wagon price of kerosine at Chicago, and Regular-Grade gasoline at refineries in Oklahoma, 1935-44, by months.

REFINING

The data from the annual survey of refinery capacity, as of January 1, 1944, show a total capacity for crude oil at completed refineries of 5,093,023 barrels. The total capacity in operation amounted to 4,709,382 barrels, and the total shut-down capacity was 383,641 barrels. The shut-down capacity included 184,534 barrels representing shut-down units at operating refineries and 199,107 barrels at plants that were completely shut down. In addition to the completed capacity, new capacity aggregating 116,070 barrels was under construction at existing plants.

The approximate distribution of the capacity at completely shut-down refineries, by principal States, was: 57,000 barrels in California, 35,000 barrels in Louisiana (representing recently built capacity about to be put in operation), 33,000 barrels in New Jersey, 21,000 barrels in Texas, 13,000 barrels in New York, 11,000 barrels in Oklahoma, and 7,000 barrels in Montana.

Summary of refinery capacity in the United States, January 1, 1940-44

Year	Number of refineries				Capacity (barrels per day)			
	Operating	Shut down	Building	Total	Operating	Shut down	Building	Total
1940.....	461	86	10	557	4,196,604	431,962	92,567	4,721,213

¹ Subject to revision.

The total crude capacity at completed refineries has risen from 4,719,000 barrels as of January 1, 1941, to 5,093,000 barrels as of January 1, 1944. During this period the total capacity at operating plants rose from 4,181,000 barrels to 4,709,000, and the total capacity at shut-down plants declined from 538,000 barrels to 384,000. Although complete data, as of January 1, 1945, are not available, the estimated crude capacity at completed refineries would amount to about 5,200,000 barrels, with about 5,030,000 barrels at operating plants.

The most important change in the greater utilization of refinery capacity during the war has been the increase in the operating ratio at active plants, although a substantial number of shut-down plants have been opened, and several large new refineries have been completed.

The operating ratio, as published in monthly reports of the Bureau of Mines, represents the percentage obtained by dividing the average daily crude run for the month by the total capacity located at operating refineries. The 12-month average of these ratios showed an annual operating ratio of 82 percent in 1940, 87 percent in 1941, 79 percent in 1942, 85 percent in 1943, and 93 percent in 1944. This ratio rose to over 94 percent in the first 4 months of 1945, with a reported capacity of about 5,030,000 barrels at operating refineries and a daily average of total crude run to stills of 4,745,000 barrels. These figures indicate that any further sustained increase in the amount of crude refined would be limited by the ability to increase the operating ratio further or by reopening the relatively small capacity of shut-down refineries that were in good condition and located near sources of available crude supply.

AVIATION GASOLINE

The Bureau of Mines initiated the collection of monthly data for aviation gasoline in October 1939. The Census of Manufacturers for 1939 showed a production of aviation gasoline at refineries for that year of about 9.4 million barrels. Exports of aviation gasoline were first shown separately in 1939 and totaled 4.2 million barrels. Assuming a substantial increase in stocks during the year, the domestic demand for aviation gasoline in 1939 was probably not much more than 3 million barrels. In 1940 the production of all grades of aviation gasoline amounted to 14.7 million barrels, and total demand was 11.3 million barrels—representing an export of 4.6 million and a domestic demand of 6.7 million. Production in 1941 rose to 21.1 million barrels and total demand to 17.7 million, with exports of 7.5 million barrels and a domestic demand of 10.2 million.

After the United States entered the war in December 1941, the expansion in the production of aviation gasoline became one of the major supply problems. A program for the construction of new plants was initiated by the Petroleum Administration for War, and the objectives as to quantity and quality continued to rise. In 1943 and 1944 the production of all grades of aviation gasoline in the United States expanded rapidly and according to published estimates materially exceeded an average of 500,000 barrels daily in 1944. The production of 100 octane or above constituted about 40 percent of the total output in 1941 and rose to about two-thirds of the total in 1944.

The expansion in the production of aviation gasoline was so great in 1944 as to offset the war decline in the civilian consumption of

motor fuel and to raise the total production and demand for motor fuel to new record levels.

MOTOR FUEL

The total demand for motor fuel since 1941 has been affected by a major decline in civilian consumption in the United States and a later rapid expansion in war requirements for our armed forces and for export to other Allied Nations. It was not until 1944 that the rise in military consumption exceeded the decline in civilian uses. The total demand for motor fuel reached a prewar peak of 695 million barrels in 1941, progressively declined to 624 million barrels in 1942 and 620 million barrels in 1943, and rose to a new record of 737 million barrels in 1944. The total increase of 117 million barrels in 1944 compared with 1943 represented gains of 68 million barrels in domestic demand and 49 million in exports. It should be noted that domestic demand includes all consumption by our armed forces at home and abroad, since overseas shipments to our armed forces are not included

FIGURE 8.—Trends of production, domestic demand, exports, imports, and stocks of motor fuel in the United States, 1918-44.

in the export figures compiled by the United States Department of Commerce.

Exports.—Exports of motor fuel, including shipments to noncontiguous Territories, almost doubled, increasing from about 52 million barrels in 1943 to 101 million in 1944. Shipments to noncontiguous Territories declined from 3.6 million barrels in 1943 to 2.3 million in 1944. Exports to foreign countries increased from 48.4 million barrels in 1943 to 98.4 million in 1944. The major part of the exports in 1943 and 1944 went to other Allied Nations engaged in the war effort. Exports to the United Kingdom rose from 31.1 million barrels in 1943 to 75.9 million in 1944. In anticipation of the landing in northern France, a considerable volume of motor fuel was included in these exports in 1944 that entered a storage pool and was returned under reverse lend-lease arrangements to our armed forces.

Comparative analyses of statistics for motor fuel in the United States in 1944, by months¹

¹Subject to revision.

Domestic demand.—The trend in the domestic demand for motor fuel in the postwar period will be a major factor in determining the total demand for all oils. The volume of gasoline consumed by civilian motor vehicles has been reduced to about two-thirds normal by rationing and the decline in the total number of vehicles in operation. The recovery of this market will depend on the future volume of new car production in relation to the higher rate of scrapping incident to the greater average age of vehicles now in use. By the end of 1944 the expansion in the military consumption of motor fuel for aviation and transport had almost offset the decline in civilian demand. Although

aviation and military demand will be much higher after the war than in the prewar period the total will be relatively small compared with automotive demand. Presumably, it will take several years for the total domestic demand for motor fuel to equal the peak demand before the war.

The domestic demand for motor fuel, including military consumption in continental United States and all shipments to our armed forces abroad, declined from about 668 million barrels in 1941 to 589 million in 1942 and 568 million in 1943 and then rose to almost 637 million barrels in 1944. Thus, even in 1944, domestic demand was 31 million barrels less than the record demand in 1941.

The primary factor in the domestic demand for motor fuel is the consumption by motor vehicles. Normally, automotive or highway uses of motor fuel constitute about 88 percent of total domestic demand. Without comprehensive data on the distribution of military consumption and stocks at home and abroad, it has not been possible to make the usual estimates of motor-fuel consumption in the United States by uses and by types of vehicles. Under war conditions, total consumption by States can only be approximated because of the large sales to the Government and the lack of information as to their final distribution.

The major changes in demand have resulted from the reduction in civilian consumption due to rationing and the unprecedented war demands for aviation and military transport and mechanized operations.

Data compiled from State tax returns by the Public Roads Administration, Federal Works Agency, show the trends of total civilian consumption for private, State, and Federal uses. The reports of the Public Roads Administration account for a total distribution for highway use, nonhighway use, and losses of 636 million barrels of motor fuel in 1941, 540 million in 1942, and 449 million in 1943. These figures indicate a decline of 187 million barrels, or over 29 percent, in civilian demand in 1943 compared with 1941. This total decline represented about 96 million barrels in 1942 and 91 million barrels in 1943.

According to the Public Roads Administration, the consumption of motor fuel for highway uses declined from 576 million barrels in 1941 to 475 million in 1942 and to 381 million in 1943—a total decline of 195 million barrels or almost 34 percent. Although no data are available by types of vehicles, the decline for private automobiles was relatively much greater than for commercial vehicles. Consumption for non-highway purposes rose from 53 million barrels in 1941 to over 59 million in 1942 and to 63 million in 1943. The most important factor in this increase was the gain in consumption for agricultural uses.

Although final figures for 1944 are not available, the monthly data indicate a moderate increase in both highway and nonhighway uses for the year.

Production.—The total production of motor fuel showed a substantial gain in 1944—from 608,180,000 barrels in 1943 to 743,484,000 in 1944—and exceeded the previous record of production in 1941 by 45,003,000 barrels. The production in 1944 comprised 385,567,000 barrels of cracked gasoline, 269,944,000 barrels of straight-run gasoline, 85,573,000 barrels of net natural gasoline and cycle-plant products (after deducting sales of liquefied gases for fuel purposes and transfers), and 2,400,000 barrels of benzol. The production of cracked gasoline increased about 71 million barrels, the production of straight-run gasoline showed a gain of 53 million barrels, and motor fuel produced at natural gasoline and cycle plants rose 11 million barrels.

Yields.—The yield of gasoline from crude petroleum declined from 44.2 percent in 1941 to 39.8 percent in 1942 and 37.1 percent in 1943 but rose to 39.4 percent in 1944. The decline in yield reflected the rapid decline in civilian consumption under rationing before the great expansion of military requirements for aviation and motor transport. However, the increase in war requirements and exports in 1944 more

¹ Subject to revision. ² Based upon crude runs to stills.

than offset the civilian decline, and the record production of motor fuel was obtained from increased crude runs and a higher yield. The yield of cracked gasoline rose from 22.0 percent in 1943 to 23.2 percent in 1944, and the yield of straight-run gasoline increased from 15.1 percent to 16.2 percent.

Prices.—There were few changes in the representative prices for gasoline in 1944, although a slight downward trend occurred toward the end of the year.

The average group-3 refinery price for Regular-grade gasoline reached the ceiling price of 6.00 cents per gallon in September 1943 and showed no change until August 1944 when it dropped to 5.93 cents per gallon. A further decline to 5.88 cents a gallon occurred in September and remained in effect for the rest of the year.

The average 50-city dealers' net price, exclusive of all taxes, rose from 10.45 cents per gallon in 1943 to 10.49 cents per gallon in 1944. It remained at 10.51 cents per gallon from January to August, inclusive, and then dropped to 10.46 cents per gallon for the rest of the year.

The average 50-cities service-station price for gasoline (including State and local taxes but excluding Federal taxes) was 19.03 cents per gallon in 1943 and 19.09 cents per gallon in 1944. It remained constant at 19.10 cents for the first 9 months of 1944 and declined to 19.05 cents for the last 3 months.

¹ National Petroleum News.

² American Petroleum Institute; compiled by The Texas Co.

There was no change in the average tax rates in 1944 compared with 1943. The average State tax remained at 4.42 cents per gallon, the Federal tax at 1.50 cents per gallon, and the average local tax at 0.05 cent per gallon. The average total for all taxes amounted to 5.97 cents per gallon in both years.

Stocks.—Stocks of finished and unfinished gasoline amounted to 94 million barrels at the end of 1941, fell to 80 million barrels at the end of 1942, showed a further decline to 75 million barrels at the end of 1943, and rose to 87 million barrels at the end of 1944. Stocks of finished gasoline were reduced 15 million barrels in 1942 and 6 million barrels in 1943. The increase of almost 10 million barrels in 1944 represented a gain of over 1 million barrels in California and an increase of less than 9 million in areas east of California.

Gasoline stocks are computed in terms of days' supply by dividing the stocks at the end of the month by the daily average demand (domestic demand plus exports) for the succeeding month. Upon this basis the days' supply represented by finished gasoline stocks on December 31 was 51.0 days at the end of 1941 compared with 55.9 days at the end of 1942, 37.9 days at the end of 1943, and 36.9 days at the end of 1944.

The stocks included in these figures represent gasoline held at refineries and bulk terminals and by pipe lines but do not include gasoline that has passed into the custody of the armed forces.

FIGURE 9.—Stocks of finished gasoline in the United States, 1941-44, by months, with figures representing days' supply at certain periods; also stocks of distillate fuel oil, 1941-44, by months.

¹ Subject to revision.² Includes stocks of finished gasoline at refineries and bulk terminals and in pipe lines.

Production and consumption by States.—The refinery production of gasoline rose from 592,425,000 barrels in 1943 to 722,718,000 barrels in 1944. Texas was the largest producer, with 220,758,000 barrels or about 31 percent of the total in 1944, compared with 29 percent in 1943. California was the second State in importance, with a total output (including some production in Washington) of 109,867,000 barrels or about 15 percent of the total in both 1943 and 1944. No other State had a production that exceeded 7 percent of the total. Production in all the important States increased in 1944 compared with 1943. The upward trend in the Coastal States was continued and the Interior States that showed a decline in 1943 increased their output in 1944.

⁷ Minnesota and Wisconsin included with Illinois.

⁸ Missouri, Nebraska, and South Dakota included with Kansas.

⁹ Tennessee included with Kentucky.

¹⁰ Rhode Island included with Massachusetts.

The lack of information on military consumption at home and abroad makes it extremely difficult to compute total consumption of gasoline by States. The American Petroleum Institute notes that since the war began certain gasoline has moved on Government bill-of-lading that bypasses State inspection and may not be recorded by the receiving State and in other cases that sales to the Government within a State may be ultimately shipped abroad.

Distribution.—The normal movements of gasoline have been subject to drastic readjustments during the war. About 131 million barrels of gasoline were shipped by boat from the Gulf Coast to the East Coast in 1941. This movement was reduced to about 34 million barrels in 1942 and amounted to only 23 million barrels in 1944. The substitution of a major tank-car movement and the expansion of pipe-line deliveries to the East Coast succeeded in maintaining the flow of gasoline to supply the restricted civilian consumption and military requirements in that district, as well as a large volume of gasoline for shipment overseas. With the concentration of tank cars in this service, the pipe lines in the Central States were operated to capacity.

Total motor fuel delivered by pipe lines rose from 111 million barrels in 1941 to 125 million in 1942, increased to 204 million barrels in 1943, and showed a further gain to 278 million barrels in 1944.

KEROSENE AND RANGE OIL

The kerosine situation improved statistically in 1944 as production, domestic demand, year-end stocks, and exports all showed gains. Imports of kerosine, which are small in relative volume and therefore unimportant from the supply angle, registered a decline in 1944.

Kerosine production increased by 8 percent from 72,270,000 barrels in 1943 to a record of 78,344,000 in 1944. This expanded output of kerosine in 1944 was entirely due to the running of a greater volume

of crude petroleum (approximately 17 percent over the 1943 total), as the yield was a negative factor, declining from 5.1 percent in 1943 to 4.7 percent in 1944. Petroleum refiners reduced the percentage yield of most products (kerosine, light and heavy fuel oil, and lubricating oil) in 1944 to increase the output of greatly needed motor fuel.

Comparative analyses of statistics for kerosine in the United States, 1943-44, by months and districts

¹ Subject to revision.

² Figures not available.

The higher production of kerosine in 1944 was the result of increased output in the Louisiana Gulf Coast, East Coast, and Texas Inland refinery districts. Kerosine production credited to the Louisiana Gulf Coast in 1944 increased by 67 percent over the 1943 quantity, while there was a recorded gain of 25 percent in the East Coast and a 36-percent expansion in the Texas Inland area. Production of kerosine in the important Texas Gulf Coast district showed little change in volume in 1944 over 1943, and furthermore the yield of the area dropped from 31 percent of the national total in 1943 to 29 percent in 1944. The output of kerosine in the Indiana-Illinois district, which is second in importance in quantity to that originating in the Texas Gulf Coast, declined by 5 percent in 1944 compared with 1943. Other areas reporting lower kerosine yields in 1944 than in 1943 were the Oklahoma-Kansas district (8 percent decline) and California, where the shrinkage was 20 percent.

The domestic demand for kerosine, which declined slightly in 1943, turned upward in 1944 in spite of rationing and distribution difficulties. Monthly figures for 1944 calculated from production, change in stocks, exports, and imports of kerosine show an indicated domestic market for 71,935,000 barrels in 1944—a 5-percent increase over the 1943 total of 68,598,000 barrels. It is impossible to present the domestic demand for kerosine by the various refinery districts, as import-export details for the corresponding areas are not available.

The export demand for kerosine, which nearly doubled in 1943 over 1942 because of improved shipping conditions, remained stationary in 1944 when the overseas market of 4,765,000 barrels varied little from the 1943 total of 4,752,000 barrels. The larger share of export kerosine went to the United Kingdom in 1944—4,167,000 barrels compared with 3,782,000 in 1943—and the quantity sent to Canada declined from 268,000 barrels in 1943 to 186,000 in 1944. Very little kerosine is imported into the United States, and the quantity has declined from 418,000 barrels in 1942 to 375,000 in 1943 and to only 147,000 in 1944.

Kerosine stocks, which declined in 1943, turned upward in 1944, when the year-end total of 11,150,000 barrels was 19 percent above the comparative inventory for 1943. The more important change took place in bulk terminal storage in 1944 which increased to 5,385,000 barrels compared with 3,887,000 in 1943. Kerosine held at refineries at the end of 1944—5,765,000 barrels—differed little from the 1943 total of 5,472,000 barrels. Days of supply of kerosine held in storage at the year end have dwindled under adverse war conditions from 61 days for 1941 to 38 days for 1943; however, there was a slight improvement in 1944, when the final inventory was sufficient for a 39-day period.

An improvement in the kerosine stock situation in the East Coast area in 1943 continued into 1944, when the final inventory of 4,359,000 barrels was 42 percent above the corresponding total for 1943. Furthermore, kerosine stocks in the important East Coast marketing area for 1944 represented 39 percent of the national total compared with a 33-percent share in 1943. A decline in kerosine stocks in the Texas Gulf Coast refinery district—the most important kerosine-producing area of the country—in evidence during the war years, continued into 1944, when the final inventory of 1,205,000 barrels was 12 percent below the comparative total for 1943. The drainage of the Texas Gulf kerosine supplies in 1944 lowered the quantity from 15 percent of the national total inventory in 1943 to 11 percent in 1944. Kerosine stocks in the Indiana-Illinois district—a supply area second only to the Texas Gulf—of 2,362,000 barrels at the end of 1944 differed only slightly from the 1943 total of 2,314,000 barrels. A pronounced drop in kerosine stocks in the Louisiana Gulf refinery district in 1943 was reversed in 1944, when a gain (985,000 barrels in 1944 compared with 577,000 in 1943) of 71 percent was reported. Lower production of kerosine in California in 1944 resulted in a 24-percent drop in inventory, the quantity declining from 658,000 barrels at the end of 1943 to 501,000 in 1944.

¹ Figures for 1944 by States not yet available.

Oil dealers report their annual sales of kerosine to the Bureau of Mines by States and principal uses. The 1943 survey, recently completed, shows total kerosine sales of 67,815,000 barrels or a small decline from the 1942 quantity of 68,690,000 barrels. A review of the kerosine demand in recent years reveals that it increased from about 60,000,000 barrels in 1939 to about 68,000,000 in 1940 and that requirements have varied but slightly from the latter volume in the past 4 years.

A heavy loss in sales of kerosine was reported for the Atlantic Coast area (39,202,000 barrels in 1943 compared with 43,735,000 in 1942), largely due to strict rationing of supplies and distribution difficulties in that area. The most serious decline in kerosine deliveries in 1943 was realized in the New England area and in the Middle Atlantic States. All other districts reported gains in sales of kerosine in 1943, the expansion being more pronounced in the South Central and Pacific Coast States.

Kerosine reported delivered as range oil declined from 39,945,000 barrels in 1942 to 38,221,000 in 1943; furthermore, the range-oil proportion of kerosine sales declined from 58 percent of the national total in 1942 to 56 percent in 1943. About 8 percent of all kerosine is sold as tractor fuel, and the total increased by 14 percent from 5,137,000 in 1942 to 5,869,000 in 1943. Most of the demand for tractor fuel was reported from the North Central and South Central States, which took 83 percent of the total in 1943. "All other uses" of kerosine increased from 23,608,000 barrels in 1942 to 23,725,000 in 1943.

There were no changes in representative kerosine prices in 1944. The quotation for 41°-43° gravity, water-white kerosine at refineries in Oklahoma of 4.38 cents a gallon dating from September 9, 1943, held throughout 1944. The tank-wagon price of kerosine at Chicago—10.6 cents a gallon—first announced December 31, 1942, remained in force throughout 1944.

FUEL OIL

War requirements approached a possible peak in 1944, and as a result domestic and export demands for fuel oil were raised to new levels. The domestic market for fuel oil in 1944 was 7 percent over the 1943 total, while the export demand was approximately 44 per-

cent above 1943. Suppliers were forced to draw on stocks again in 1944 to satisfy the trade, although production, transfers from crude, and imports were all higher than in 1943. The indicated domestic demand for fuel oil in 1944 was 720,337,000 barrels compared with 675,118,000 in 1943. Most of the increase was limited to the residual grades, which expanded by 9 percent from 467,008,000 barrels in 1943 to 510,797,000 in 1944, but the 1944 total for the distillate or light fuel oils of 209,540,000 barrels was less than 1 percent above the 1943 volume of 208,110,000 barrels. Exports of fuel oil increased from 39,851,000 barrels in 1943 to 57,172,000 in 1944; however, the gain was confined to the distillate oils, which expanded by 74 percent from 24,957,000 barrels in 1943 to 43,345,000 in 1944, whereas the foreign market for heavy fuel oils dropped by 7 percent from 14,894,000 barrels in 1943 to 13,827,000 in 1944.

A 19-percent increase in the domestic demand for fuel oil in the first quarter of 1944 over the corresponding period of 1943 was largely the result of higher industrial and military requirements as the weather, being milder, was not a factor. The indicated demand for residual grades, which are used largely as fuel in heavy industries, increased by 24 percent from 105,457,000 barrels in the opening quarter of 1943 to 130,936,000 for the same period of 1944, but the market for distillate fuel oils, about half of which are used for space heating, expanded at a lesser rate (9 percent) from 61,255,000 barrels in the first 3 months of 1943 to 66,620,000 in the 1944 quarter. Mild weather and the tapering off of the heating season resulted in a decline in the light fuel-oil demand in the second quarter of 1944, when the total of 44,384,000 barrels was 3 percent below corresponding requirements of 45,725,000 in 1943. Industrial consumption of heavy fuel oil remained at a fairly high level in the April-June quarter of 1944, the demand of 125,472,000 barrels being 11 percent over the total of 113,379,000 for the same period of 1943.

² Interstate Commerce Commission; total includes Diesel fuel.

³ Figures not available.

⁴ Federal Power Commission.

The market for fuel oil was unusually high in the third quarter of 1943, and 1944 requirements did not reach the same level. The indicated demand for distillates—39,424,000 barrels in the quarter—was 12 percent below the 1943 total of 44,802,000, but the decline for residual grades was less pronounced—only 2 percent—or from 118,722,000 barrels in the third quarter of 1943 to 115,841,000 for the corresponding months in 1944. The demand for heating oils again became a factor in the closing quarter of 1944, when deliveries of light grades of fuel oil of 59,112,000 barrels were 5 percent over 1943 requirements of 56,328,000, and residual grades totaling 138,548,000 barrels represented an expansion of 7 percent over the 1943 market of 129,540,000 barrels.

The annual survey of the Bureau covering the distribution of fuel-oil sales by States and uses in 1944 is incomplete, so all that is known about the principal demands at this time is taken from monthly releases of Government and other agencies. An estimate based on monthly statements of the Interstate Commerce Commission places fuel-oil requirements of the railroads at 125,000,000 barrels in 1944, a total little different from 1943 purchases of 124,886,000 barrels. The market for fuel-oil bunkers for vessels plying in foreign trade continued to expand in 1944 as it did in 1943, according to statistics compiled by the Bureau of the Census. That agency reported a total of 69,753,000 barrels of fuel oil loaded on vessels for bunkers at American continental ports in 1944—a 46-percent gain over the 1943 demand of 47,880,000 barrels. Requirements for bunker oil by vessels operating in coastwise traffic probably did not expand proportionately in 1944; however, it is believed that total fuel-oil bunkers—both foreign and coastwise—may have reached 98,000,000 barrels in 1944 or a gain of 34 percent over 1943 deliveries of 73,265,000 barrels.

Monthly publications of the Federal Power Commission show consumption of 20,814,000 barrels of fuel oil by public-utility power plants in 1944, a 15-percent increase over the 1943 total of 18,036,000 barrels. Manufactured-gas companies used 18,390,000 barrels of fuel oil in 1943, according to statistics released by the American Gas Association, and it is believed that 1944 requirements probably rose to 19,500,000 barrels. This estimate for the manufactured-gas companies in 1944 plus the known consumption of 20,814,000 barrels of fuel oil by electric-power plants indicate a total demand of approximately 40,300,000 in 1944 for the public utilities—a 9-percent gain over 1943 purchases of 36,812,000 barrels.

Oil companies reported sales of 99,344,000 barrels of fuel oil to smelters, mines, and manufacturing plants in 1943. In view of conservation, forced conversion to other fuels, and supply difficulties in some areas, it is not anticipated that the 1944 demand for fuel oil by these industries, when known, will have shown any great increase and the total is estimated at 103,000,000 barrels—a 4-percent gain over 1943.

Deliveries of fuel oil for space heating dropped in 1943 owing to strict enforcement of ration regulations, shifts to other fuels, distribution difficulties, and the diversion of supplies for military use; and furthermore, 1944 totals when available may show another small decline. It is estimated that deliveries of fuel oil for heating totaled 151,000,000 barrels in 1944 compared with 155,251,000 in 1943. The 1944 quantity represents 110,000,000 barrels of distillate grades

(112,581,000 in 1943) and 41,000,000 of heavy fuel oil (42,670,000 in 1943) for the heating of buildings.

The use of No. 1 fuel oil for range burners showed a gain of 18 percent in 1943 over 1942, as it is believed that some users turned more to this kind of heating in order to save fuel ordinarily consumed in central heating plants. Deliveries of No. 1 fuel oil for range burners

FIGURE 10.—Sales of fuel oil and range oil in the United States, 1934-43, by uses.

increased from 4,978,000 barrels in 1942 to 5,876,000 in 1943, and it is estimated that the 1944 demand was 6,000,000 barrels or over.

Crude-oil production increased about 11 percent in 1944 compared with 1943, and runs to stills were approximately 17 percent over the 1943 total, so it is believed that oil companies consumed about 54,000,000 barrels of fuel oil in their field, pipe-line, and refinery operations in 1944—about a 13-percent gain compared with 1943 requirements of 48,007,000 barrels. All other uses of fuel oil, including military demands, probably totaled 143,000,000 barrels in 1944.

¹ Includes Navy grade and crude oil burned as fuel.² Figures for 1944 not yet available.³ This total may involve some duplication due to rehandling of fuel oil initially sold to the Government.

The varying demands for fuel oil by principal uses for the years 1934-43 are presented graphically in figure 10. The lengths of the different columns represent totals for the respective years as reported in the Bureau's annual fuel-oil survey. Distillate fuel oil, residual fuel oil, and kerosine used as range fuel are included.

Exports of fuel oil increased by 44 percent from 39,851,000 barrels in 1943 to 57,172,000 in 1944; however, the expansion was limited to the distillate grades, which rose by 74 percent to a record volume of 43,345,000 barrels in 1944 compared with 24,957,000 in 1943. The foreign market for residual fuel oil has fluctuated narrowly in recent years and declined by 7 percent from 14,894,000 barrels in 1943 to 13,827,000 in 1944. The large increase in distillate fuel-oil exports in 1944 resulted from lend-lease requirements, the United Kingdom receiving 87 percent of the total, or 37,763,000 barrels, in 1944 compared with 16,797,000 in 1943. Canada also was shipped a larger quantity of light fuel oil in 1944—1,714,000 barrels against 423,000 in 1943. Conversely, consignments of distillate grades of fuel oil to Oceania and Australia declined from 4,677,000 barrels in 1943 to 1,197,000 in 1944. Shipments of light fuel oil to U. S. S. R. made another gain, increasing from 264,000 barrels in 1943 to 312,000 in 1944.

Movements of heavy fuel oil to the United Kingdom and to Canada declined greatly in 1944—the quantity credited to the United Kingdom dropping from 10,683,000 barrels in 1943 to 6,058,000 in 1944; and the total for Canada slumped for a second consecutive year from 907,000 barrels in 1943 to 496,000 in 1944. Exports of heavy fuel oil to Mexico, although relatively unimportant, increased from 584,000 barrels in 1943 to 627,000 in 1944. Some residual fuel oil is sent to Cuba, usually for reshipment, and the total in this movement expanded from 680,000 barrels in 1943 to 2,245,000 in 1944.

A 17-percent increase in runs of crude petroleum to stills enabled refiners to produce a record quantity of fuel oil in 1944, when the total of 700,607,000 barrels was 11 percent above the 1943 output of 628,822,000 barrels. The larger production of fuel oil in 1944 was due entirely to the greater volume of crude processed at refineries, as the percentage yield (42.1 percent in 1944 compared with 44.0 percent in 1943) was reduced to increase the output of motor fuel, especially aviation grades. The yield of distillate fuel oil increased from 211,516,000 barrels in 1943 to 239,152,000 in 1944, whereas residual grades expanded from 417,306,000 barrels in 1943 to 461,455,000 in 1944. It should be noted that the production of light fuel oil increased by 13 percent in 1944 compared with an 8-percent increment in 1943, but the 1944 total for heavy fuel oil was only 11 percent over 1943 against a 16-percent gain recorded in 1943.

All refinery districts ran more crude to stills in 1944 than in 1943; therefore, declines in fuel-oil production in 1944 reported for several areas were entirely due to lower percentage yields. The fuel-oil supply situation was critical in the East Coast district in 1944; there the output of light fuel oil was raised by 23 percent (46,763,000 barrels in 1944 compared with 38,077,000 in 1943), in spite of a reduced percentage yield, by running 32 percent more crude to stills. The production of heavy fuel oil in the East Coast increased from 56,004,000 barrels in 1943 to 79,964,000 in 1944—a 43-percent gain. This expanded output of residuals in 1944 was mainly the result of higher runs to stills and an increased percentage yield (31.1 percent in 1944 compared with 28.8 percent in 1943); however, the processing of a larger volume of South American crude of high residual-fuel-oil content was also a factor.

The Texas Gulf Coast refinery district produces more distillate fuel oil than any other area and is second only to California as a

source of residual grades. Distillate fuel oil originating in the Gulf Coast area increased from 64,506,000 barrels in 1943 to 73,935,000 in 1944 and represented about 31 percent of the national total for both years. The 1944 quantity was 15 percent above the 1943 output compared with a 6-percent gain in 1943 over 1942. As the percentage yield for distillate fuel oil dropped in the district (18.1 percent in 1944 compared with 19.3 percent in 1943), the higher production must be credited entirely to a 22-percent gain in runs to stills. Refineries operating in the Texas Gulf Coast turned out 97,683,000 barrels of residual fuel in 1944, a gain of 13 percent over the 1943 production of 86,549,000 barrels. The increase in 1944—as with the distillate grades—was entirely the result of higher crude runs, as the percentage yield declined from 25.8 percent in 1943 to 23.9 percent in 1944.

¹ Includes distillate fuel oil, residual fuel oil, and some crude oil burned as fuel.

² Figures for 1944 not yet available.

The 1944 production of distillate fuel oil in the Indiana-Illinois refinery district—34,544,000 barrels—varied little from the 1943 quantity of 34,631,000 barrels. A 5-percent reduction in the output of heavy fuel oil in this district (56,890,000 barrels in 1944 compared with 59,621,000 in 1943) forced the area down from third to fourth as a producing district, and the East Coast moved up.

More heavy fuel oil—30 percent of the national total—is produced in California than in any other refinery district, and it ranks fourth as a source of distillate grades. The output of distillate fuel oil in California in 1944—29,382,000 barrels—was only 2 percent above the 1943 quantity of 28,881,000 barrels, and compares with an 18-percent expansion realized in 1943. The smaller percentage gain in 1944 resulted largely from a decline in the yield from 10.9 percent in 1943 to 10.0 in 1944. Refiners operating in California produced 135,946,000 barrels of residual fuel oil in 1944 compared with 126,856,000 in 1943. The smaller rate of gain (7 percent) for heavy fuel oils in 1944 compared with a 22-percent increase in 1943 was almost entirely, as with the light grades, connected with a lower yield, 46.1 percent in 1944 against 48.1 percent in 1943.

Gains and losses in fuel-oil production in 1944 for refinery districts where the volumes are relatively unimportant were as follows: Appalachian, distillate fuel oil 2 percent below and residual fuel oil 11 percent below the 1943 quantity; Oklahoma-Kansas, light fuel oil 13 percent higher and heavy grades 4 percent less than the 1943 output; Texas Inland, distillate 13 percent and residual 5 percent over the 1943 total; Louisiana Gulf Coast, a 64-percent gain in light fuel oil production and a 28-percent expansion for residual grades over 1943; Arkansas and Louisiana Inland, a 7-percent loss for distillate fuel oils and a 12-percent decline for heavy fuel oil; and the Rocky Mountain district, an 18-percent gain for light grades and a 10-percent rise in the output of residual fuel oil over the 1943 volume. The high rate of gain shown for distillate fuel oil in the Louisiana Gulf area was the result of a 48-percent rise in runs to stills as well as to an increase in yield from 16.6 percent in 1943 to 18.4 percent in 1944. The percentage yield for residuals dropped in 1944, so the larger output for the heavier grades in this district must be credited to the increased volume of crude processed in 1944.

Some crudes, either low in gasoline content or on location in field operations, are used direct as fuel without any refining. Such crudes are recognized as an added supply of fuel oil and are termed "transfers" in fuel-oil accounting. During the war period and the resulting pinch for fuel oil, transfers have doubled from 15,482,000 barrels in 1941 to 31,757,000 in 1944, and furthermore, the 1944 total is 17 percent above the quantity reported in 1943—27,157,000 barrels.

Heavy crude oil consumed as fuel on oil leases or in industrial plants is covered in transfers to the residual fuel-oil account, and light crudes used in some areas as fuel in the operation of pipe lines are added to distillate fuel oils. Transfers of high-gravity or light crudes increased from 3,070,000 barrels in 1943 to 3,242,000 in 1944—a 6-percent gain, whereas heavy or low-gravity crudes used as fuel expanded by 18 percent, from 24,087,000 barrels in 1943 to 28,515,000 in 1944. Most of the light crudes are consumed as fuel in areas east of California, where the total of 3,163,000 barrels for 1944 differed little from the 1943 quantity of 3,051,000 barrels. Very little light crude is burned

as fuel in California—only 19,000 barrels in 1943 and 79,000 in 1944. The larger share of the heavy crude reported under "transfers" is credited to California, the volume increasing by 23 percent, from 18,861,000 barrels in 1943 to 23,177,000 in 1944. Transfers of heavy crude to the fuel-oil account for areas east of California totaled 5,226,000 barrels in 1943 and 5,338,000 in 1944.

Imports of fuel oil, greatly depressed in 1942 because of enemy submarine activities and the lack of tankers for civilian use, rebounded to a normal level in 1943 and continued to expand nominally in 1944, when total receipts of fuel oil from foreign sources of 43,649,000 barrels were 3 percent over 1943 imports of 42,479,000 barrels. The supply of residual fuel oil was critical in the Atlantic Coast area in 1944; consequently, an effort was made to bring in stocks from foreign sources, with the result that the total of 36,553,000 barrels approached the prewar level of 1941 (37,369,000 barrels) and exceeded 1943 receipts of 27,210,000 barrels by 34 percent. Imports of distillate fuel oil (7,096,000 barrels in 1944) were 54 percent below the unusually high total of 15,269,000 recorded for 1943; however, the deflated 1944 quantity for distillate grades was still well above prewar receipts from foreign sources.

Imported fuel oil supplies a very small proportion of the total domestic and export demand. Distillate fuel oil of foreign origin satisfied 2 percent of the total market in 1942, then with the record receipts in 1943, the share rose to 7 percent; however, it declined to 3 percent of the total in 1944, when imports were lower by over 50 percent. The volume of residual fuel oil received from abroad has expanded noticeably in recent years, and the share of the total market it has supplied has mounted from 4 percent in 1942 to 6 percent in 1943 and to 7 percent in 1944.

Practically all the fuel oil imported into this country is credited to the West Indian island of Curaçao, where petroleum refineries, running on Venezuelan crude, are located. Some small quantities are also received from Venezuela, Trinidad, Mexico, and Canada.

The fuel-oil stock situation showed great improvement in 1944, even though oil companies were called upon to supply record domestic and export demands. Liquidations of fuel-oil stocks totaling approximately 25,500,000 barrels necessary in 1942 and 16,500,000 in 1943 were not repeated in 1944, when the year-end total of 88,716,000 barrels was only about 1,500,000 below the comparative inventory for 1943 of 90,212,000 barrels. The small shrinkage in 1944 was a net loss, as stocks of distillate grades declined by 8 percent from 41,728,000 barrels for 1943 to 38,333,000 at the end of 1944, while the heavy fuel-oil inventory increased by about 4 percent from 48,484,000 barrels for 1943 to 50,383,000 as of December 31, 1944. The percentage loss for distillate stocks in 1944 (8 percent) differed little from comparative rates of liquidation of 7 percent for 1943 and 9 percent for 1942; however, the percentage gain for residuals in 1944 (4 percent) is in contrast to percentage declines of 22 percent in 1943 and 26 percent in 1942. Both refinery and bulk-terminal inventories of distillate fuel oil dropped in 1944, but comparative items for heavy fuel oil were higher in 1944 than in 1943. Light grades of fuel held at refineries shrunk by 10 percent from 27,816,000 barrels for 1943 to 25,070,000 at the 1944 year end. The loss in bulk-terminal storage of distillates was less marked—a 5-percent decline—or from 13,912,000

² Subject to revision.

³ Figures not available.

barrels in 1943 to 13,263,000 in 1944. Oil companies held 40,356,000 barrels of residual fuel oil at their refineries in December 1944 compared with 38,855,000 for 1943 (a 4 percent rise), and supplies at bulk terminals made a similar percentage gain from 9,629,000 barrels in 1943 to 10,027,000 at the close of 1944.

Distillate fuel oil withdrawn from storage supplied a little over 1 percent of the total domestic and export market in 1943 and 1944, whereas heavy fuel oil diverted from stocks satisfied about 3 percent of the marketed quantity in 1943 and no proportion of it in 1944. Distillates held in storage at the end of 1944 were sufficient for 47 days of domestic supply at the December rate of demand in contrast to a 59-day reserve on hand at the close of 1943. The comparative days of supply for residuals dropped from 33 for 1943 to 31 for 1944.

The larger share of distillate fuel-oil stocks is held in the East Coast, although the proportion declined from 30 percent of the national total in 1943 to 25 percent at the close of 1944. Quantitatively the East Coast inventory for light fuel oils dropped by 22 percent from 12,293,000 barrels in 1943 to 9,621,000 in 1944. The slump in East Coast distillate stocks in 1944 is in contrast to a 46-percent gain reported for 1943 over an unusually low reserve held at the end of 1942. Residual fuel oils stored in the Atlantic Coast area are less important nationally; however, the total has been built up from 3,613,000 barrels for the critical war year of 1942 to 6,341,000 in 1943 and to 6,831,000 in December 1944.

More residual fuel oil is held in the California area than in any other part of the country, but under the pressure of war demands the quantity dropped drastically (by 40 percent) in 1943 and to a lesser extent (by 2 percent) in 1944. Stocks of heavy fuel oil in California declined from 26,608,000 barrels (55 percent of the national total) for 1943 to 26,047,000 (52 percent of the national total) at the close of 1944. Considerable quantities of distillate fuel oil are also stored on the west coast, although the total has declined from 12,185,000 barrels in 1942 to 10,674,000 in 1943 and to 9,259,000 in 1944.

Light fuel oil held in storage in the Texas Gulf refinery district reached a high level in 1942 (12,336,000 barrels), as this fuel could not be moved to East Coast consuming areas under prevailing transportation difficulties. Traffic conditions were partly remedied in 1943 and 1944, so that there was a more normal flow of supplies to eastern markets, and consequently stocks of distillate fuel oil in the Texas Gulf area dropped to 7,452,000 barrels in 1943 and rose only nominally to 7,549,000 by the end of 1944. Rising production of residual fuel oil in the Texas Gulf Coast has made it possible for year-end inventories in the district to increase from 6,275,000 barrels in 1942 to 8,136,000 in 1943 and to 9,974,000 in 1944.

Fairly important stocks of distillate fuel oil are carried in the Indiana-Illinois refinery district, and inventories there have increased in recent years to 6,419,000 barrels at the close of 1944—a 9-percent expansion over the comparative total for 1943 of 5,873,000 barrels. Holdings of residual grades of fuel oil in the same area have also shown small gains rising to 3,060,000 barrels at the end of 1944 against 2,983,000 for 1943; however, the 1944 volume is still well below prewar quantities.

³ Figures not available.

Stocks of fuel oil credited to other refinery districts are relatively unimportant. Percentage gains and losses in 1944 year-end inventories over 1943 for distillate fuel oil in these remaining areas were as follows: Oklahoma-Kansas, 19 percent up; Arkansas and Louisiana Inland, 14 percent up; Appalachian, 32 percent down; Texas Inland, less than 1 percent down; Louisiana Gulf, 1 percent down; and Rocky Mountain, 2 percent down. Similar percentage stock changes for heavy fuel oils in 1944 were: Appalachian, 85 percent up; Oklahoma-Kansas, 35 percent up; Texas Inland, 3 percent down; Louisiana Gulf, 19 percent down; Arkansas and Louisiana Inland 29 percent down; and Rocky Mountain, 30 percent down.

Tanker movements of fuel oil from California to eastern areas of the country have not been reported for several years, and there was no revival of this trade in 1944. The California refinery district (California, Oregon, Washington, Arizona, and Nevada), however, ships some minor quantities of fuel oil by railroads and trucks to neighboring Western States. Distillate fuel oils distributed over these land routes increased from 435,000 barrels in 1943 to 492,000 in 1944, while the volume of residual grades declined from 215,000 barrels in 1943 to 182,000 in 1944. There is also a compensating movement of small amounts of fuel oil into the California marketing area from other States, and this traffic expanded noticeably in 1944 as the war in the Pacific became accelerated. Domestic fuel oils shipped into the California refinery district totaled 275,000 barrels of distillates in 1944 against 19,000 in 1943 and 571,000 barrels of residual types in 1944 compared with 322,000 in 1943.

Source: Petroleum Industry War Council and Petroleum Administration for War.

In normal times considerable quantities of fuel oil are moved by tanker from Gulf Coast ports to East Coast markets. This waterborne traffic has dwindled during the present emergency, and consequently other means of transportation—tank cars, barges and pipe lines—have been used instead. Records compiled by the Petroleum Industry War Council and the Petroleum Administration for War show that the volume of this flow of fuel oil from districts 2 and 3 into the East Coast (district 1) increased somewhat in 1943 over 1942, although there was a decline in 1944 compared with 1943. Light fuel oils in this movement declined by 9 percent from 67,441,000 barrels in 1943 to 61,488,000 in 1944, while the volume of residual grades

dropped by one percent from 75,046,000 barrels in 1943 to 74,298,000 in 1944. The quantity of distillate fuel oil moved by tankers from the Gulf Coast to the Atlantic seaboard continued to decline from 20,341,000 barrels in 1942 to 14,881,000 in 1943 and to 10,980,000 in 1944. The total for residual grades slumped from 27,149,000 barrels in 1942 to 12,996,000 in 1943; however, it increased to 18,300,000 in 1944. The tank-car movement of light fuel oil into the East Coast marketing area declined from 48,910,000 barrels in 1943 to 28,914,000 in 1944, but this loss was largely made up by pipe-line receipts of 18,300,000 barrels in 1944 against none moved by that method in 1943. The railroads hauled 58,035,000 barrels of heavy fuel oil to the East Coast in 1943 and only 51,972,000 in 1944. Some relatively unimportant quantities of fuel oil were shipped to the East Coast area in barges and small tankers operating in coastal and inland waters. The detailed items for all these movements of fuel oil from districts 2 and 3 into district 1 are given in the accompanying table.

There were no changes in tanker rates in 1944 on fuel oil shipped from the Gulf Coast to North Atlantic ports, not east of New York. Charges of 42 cents a barrel for No. 2 fuel oil and 48 cents for crude and residual oils (10°-19.9° gravity) dating from January 1942 were continued throughout 1944. A surcharge of 200 percent allowed by the War Shipping Administration to cover increased wartime expenses, initiated in April 1942, was still in effect during 1944.

¹ Platt's Oil Price Handbook.

² No quotations posted.

The price of representative fuel oils in 1944 remained at 1943 levels except for some changes announced for residual grades including Bunker C in the Atlantic and Gulf Coast areas and for ships' Diesel fuel in California. During the period March 9, 1943, to August 1, 1944, quotations for Bunker C (and other heavy fuel oils) were based on the gravity and for New York harbor ranged from \$1.65 to \$2.07 a barrel (\$1.86 average), and for Gulf Coast ports they varied from 85 cents to \$1.27 or an average of \$1.06 a barrel. Amendment 13 to price schedule MPR 88 of the Office of Price Administration, effective August 1, 1944, changed the quotations for heavy fuel oil from the former range based on varying gravities to a fixed price irrespective of the gravity. The new price for Bunker C at New York was placed at \$1.77 a barrel and at 97 cents a barrel at Gulf ports. Quotations on Bunker C at California terminals of \$1.10 a barrel dating from June 1943 remained in force all during 1944.

The quoted price on Diesel fuel for ships' bunkers at New York harbor—\$2.78 a barrel—in force since September 1942 held throughout 1944, and the price for the same grade at Gulf ports—\$1.65 a barrel—effective since December 1942, was also unchanged in 1944. The California price of Diesel fuel for ships averaging \$1.43 a barrel, dating from May 1943, was raised to a fixed quotation of \$1.45 a barrel on January 21, 1944, and this value was maintained for the rest of the year.

The price of No. 2 straw fuel oil at refineries in Oklahoma was pegged at 3.63 cents a gallon in December 1942, and this quotation remained in force during all of 1943 and 1944.

Average retail prices of fuel oil were fairly stable in 1944, as indicated by monthly quotations compiled for a number of cities and published by the Bureau of Labor Statistics, United States Department of Labor. The consumers average price for No. 2 fuel oil at Chicago of 7.96 cents a gallon in force since December 1942 remained unchanged until August 1944 when it declined to 7.76 cents a gallon and then to 7.45 cents in September, where it remained until the end of the year. The declines were merely market fluctuations, as no changes were ordered by the Office of Price Administration at the time. A retail quotation for No. 2 in New York City of 9.09 cents a gallon, going back to December 1942, was held at the same level for all of 1943 and 1944.

LUBRICATING OIL

The demand for lubricating oil totaled 40,322,000 barrels in 1943 and rose to 41,072,000 barrels in 1944. Exports of 8,889,000 barrels in 1944 were approximately the same as in 1943, but almost 2 million barrels below the prewar level.

The domestic demand for lubricating oil rose from 31,459,000 barrels in 1943 to 32,183,000 barrels in 1944, exceeding the demand in 1941 by about 2 million barrels. The sharp decline in civilian automotive use has been offset by the increased demand for industrial lubricants and the expansion in aviation and military transport requirements.

The yield of lubricating oil from crude declined from 2.9 percent in 1942 to 2.7 percent in 1943 and 2.5 percent in 1944. This decline in yield reflects the fact that total production has increased less rapidly than total crude runs to stills.

Refinery stocks of lubricating oil, after a decline of 1.6 million barrels in 1943, showed a minor gain in 1944 and amounted to 7,815,000 barrels at the end of the year.

The refinery production of lubricating oil rose to 41,106,000 barrels in 1944. Since 1941 the most notable changes in the production of lubricating oil by districts have been the decline in the Appalachian area and substantial increases in the Texas Gulf Coast, Oklahoma, Kansas, Arkansas and Louisiana Inland, and California districts. Production in the Appalachian district declined from 5,652,000 barrels in 1943 to 5,278,000 in 1944. Production in the East Coast district rose from 7,205,000 barrels in 1943 to 8,237,000 barrels in 1944 but was still below the level of 1941. In the Texas Gulf Coast, production increased from 9,745,000 barrels in 1943 to 10,614,000 barrels in 1944.

¹ National Petroleum News.**OTHER PRODUCTS**

Wax.—The total demand for wax increased from 700 million pounds in 1942 to 759 million in 1943 and 796 million in 1944. Imports have declined since 1940 and ceased in 1944.

The domestic demand for wax has exceeded all previous levels owing to war uses in the protection and weather-proofing of materials shipped abroad. Domestic demand, including all of our military requirements at home and abroad, has risen from 357 million pounds in 1940 to 634 million in 1944—a gain of 277 million pounds or 80 percent.

Exports of wax amounted to 173 million pounds in 1943 and 162 million in 1944. The largest exports in 1944 were 64 million pounds to the United Kingdom, 19 million to Canada, and 13 million to Colombia.

The East Coast refinery district produced almost 36 percent of the output of wax in 1944. The principal changes in production, by districts, in 1944 compared with 1943 were gains of 42 million pounds in the East Coast, 12 million in California, and 6 million in the Louisiana Gulf Coast and Oklahoma-Kansas districts. The principal decline was 14 million pounds in the Texas Gulf Coast.

Coke.—The production of petroleum coke rose from 1,388,000 short tons in 1943 to 1,803,000 tons in 1944 or 30 percent. A withdrawal of 71,000 tons from storage raised total demand to 1,874,000 tons in 1944. Exports declined from 314,000 tons in 1943 to 209,000 tons in 1944, and domestic demand increased from 1,050,000 tons in

1943 to 1,665,000 in 1944. Both production and consumption in 1944 exceeded the prewar level.

Normally, a substantial amount of petroleum coke was consumed for domestic heating purposes, but most of the supply was reserved for electrode manufacture to meet war requirements, particularly in the aluminum industry. These restrictions were partly removed in 1944, and some coke was released for heating purposes.

The principal refinery districts producing petroleum coke, in order of their importance in 1944, were the Indiana-Illinois, Texas Gulf Coast, Louisiana Gulf Coast, Oklahoma-Kansas, Texas Inland, and California districts. The Indiana-Illinois district produced 61 percent of the total in 1943 and 62 percent in 1944.

³ Figures not available.

Asphalt and road oil.—The domestic demand for petroleum asphalt rose from 6,618,500 short tons in 1943 to 6,892,800 in 1944, and exports increased from 98,900 to 131,100 tons. Refinery production amounted to 6,996,100 tons in 1944—a gain of 239,400 tons or 3.4 percent. Imports of asphalt have declined steadily since 1941 and amounted to only 90,700 tons in 1944.

The domestic consumption of road oil has been curtailed by the increasing requirements for residual fuel oil. Consumption has decreased from 8,980,000 barrels in 1941 to 2,295,000 in 1943 and to 1,560,000 in 1944.

Detailed statistics for asphalt and road oil appear in the chapter on Asphalt and Related Bitumens.

Still gas.—The production of still gas increased from 312,318 million cubic feet in 1943 to 368,061 million in 1944, or 18 percent. The largest production of still gas by refinery districts in 1944 was 115 billion cubic feet in the Texas Gulf Coast, 66 billion in Indiana, Illinois, Kentucky, etc., 51 billion in the East Coast, 29 billion in the Louisiana Gulf Coast, and 25 billion in Oklahoma, Kansas, etc. Over 90 percent of the still gas is used for fuel at refineries. It represents, however, a potential source from which increasing amounts of liquefied gas and other products may be recovered.

Miscellaneous oils.—The domestic demand for this group of products has risen from 11,862,000 barrels in 1941 to 30,857,000 barrels in 1944. Probably at least 80 percent of the products in this group are included under the general classification of liquefied gases for fuel uses and for chemical and rubber manufacture; but a substantial increase has occurred in other products, such as toluene and other war materials.

The indicated supply of these products includes transfers of liquefied petroleum gases from natural gasoline and cycle plants that are not included in motor-fuel demand but represent deliveries of these materials for fuel purposes. These transfers rose from 6,281,000 barrels in 1941 to 11,589,000 in 1943 and to 12,652,000 in 1944. The remaining products represent the production of liquefied gases and of other miscellaneous oils at refineries. The total refinery production of these oils rose from 6,266,000 barrels in 1941 to 9,660,000 in 1943 and 18,436,000 in 1944. The refinery output, by classes, is shown for 1942 and 1943, but figures are not yet available for 1944. The indicated production of all types of liquefied gases at refineries rose from 4,755,000 barrels in 1941 to 6,279,000 in 1943.

WORLD PRODUCTION²

The world production of crude petroleum continued its steadily rising trend (interrupted only in 1930-32, 1938, and 1942). Losses and curtailments in civilian demand during the present war were more than compensated by war demand, and the net result was wider use and greater consumption.

The Western Hemisphere contributed 79 percent of the total world production. The United States alone supplied 64 percent of the world output and Venezuela 10 percent. In the Eastern Hemisphere the U. S. S. R. furnished 10½ percent of the world total.

In the United States, war demands, in spite of rationing civilian use, raised the national crude production 11 percent in 1944 over 1943. Mexico increased its petroleum output 8 percent from 1943 to 1944.

Improved shipping conditions permitted Venezuela to enlarge its petroleum production 45 percent and Colombia 68 percent from 1943 to 1944. On the other hand, the difficulty of obtaining drilling equipment retarded petroleum production in Argentina, in spite of vigorous prospecting by the Government-controlled enterprise that dominated the industry.

Statistical information on the petroleum industry of Europe is still scanty and none too reliable. The U. S. S. R. showed recovery from the German invasion and the temporary capture of certain fields. On the other hand, the Rumanian decrease may be traced to the ravages of bombardment and invasion. In Germany, Austria, and Hungary efforts to step up production were evidently successful.

In the Far East data on petroleum production of Asia are largely

² By A. H. Redfield, Petroleum Economics Division, Bureau of Mines.

conjectural. In the Middle East, however, victory in North Africa and clearing of the Mediterranean permitted Iran and Irak to expand their petroleum output.

Crude petroleum produced in principal countries of the world, 1939-44, in thousands of barrels

FOREIGN TRADE¹

IMPORTS

Imports of mineral oils, crude and refined, into continental United States increased 45 percent from 1943 to 1944. They constituted 5 percent of the total new supply in continental United States in 1944 compared with 4 percent in 1943.

Crude petroleum, residual fuel oil, and distillate fuel oil made up 89 percent of the total imports in 1943 and 96 percent in 1944. Virtually all these imports came from ports of the Caribbean Sea and the Gulf of Mexico. Venezuela supplied 68 percent of the crude petroleum imported in 1943 and 82 percent in 1944, Colombia 22 percent in 1943 and 17 percent in 1944, and Mexico 10 percent in 1943 but only 1 percent in 1944. Of the residual fuel oil imported in 1943, Netherlands West Indies furnished 95 percent and Trinidad 4 percent; in 1944 Netherlands West Indies shipped 98 percent and Trinidad less than 1 percent. Of the distillate fuel oil imported, Netherlands West Indies sent 84 percent in 1943 and 69 percent in 1944; Venezuela 7 percent in 1943 and 12 percent in 1944; Mexico 6 percent in 1943 and 14 percent in 1944; and Trinidad 1 percent in 1943 and 6 percent in 1944.

² Subject to revision.

EXPORTS

Continental United States continued to be a net exporter of mineral oils. The excess of petroleum exports over petroleum imports increased from 86,545,000 barrels in 1943 to 116,655,000 barrels in 1944.

¹ By A. H. Redfield, Petroleum Economics Division, Bureau of Mines.

In crude petroleum, an excess of exports over imports amounting to 27,509,000 barrels in 1943 was converted to an excess of imports over exports totaling 10,567,000 barrels. On the other hand, the excess of exports of refined oils increased from 59,036,000 barrels in 1943 to 127,222,000 barrels in 1944. Of the refined oils, only residual fuel oil showed greater imports than exports. Imports of residual fuel oil exceeded exports by 12,316,000 barrels in 1943 and by 22,726,000 barrels in 1944.

In absolute amounts, exports and territorial shipments of mineral oils, both crude and refined, were 39 percent larger in 1944 than in 1943. The principal gains were in outward shipments of motor fuel, followed by distillate fuel oil. In contrast, exports and territorial shipments of crude petroleum and of residual fuel oil were less in 1944 than in 1943.

Of the exports of major refined mineral oils, 70 percent in 1943 and 78 percent in 1944 went to Europe. The United Kingdom received 67 percent of the total in 1943 and 75 percent in 1944, and the U. S. S. R. most of the remainder.

Other North American countries received 8 percent of the total exports in 1943 and 6 percent in 1944. Canada received 5 percent of the whole in 1943 and 3 percent in 1944.

The share of Oceania in the mineral-oil exports of the United States declined from 16 percent in 1943 to 5 percent in 1944.

Major petroleum products shipped from continental United States, by countries of destination, and shipments to and exports from noncontiguous Territories, 1948-44¹

¹ Exports of crude as reported to Bureau of Mines; export and shipments of refined products compiled from records of U. S. Department of Commerce; figures may differ slightly from those used throughout other sections of this report.

² Includes benzol, natural gasoline, and antiknock compounds.

³ Subject to revision.

INTERCOASTAL SHIPMENTS ¹

Receipts of mineral oils, crude and refined, on the East Coast from Gulf Coast ports were 25 percent larger in 1944 than in 1943, but amounted to only 18 percent of the corresponding shipments of 1941. Gasoline was the largest single item in these shipments and constituted 30 percent of the total shipments in 1944, compared with 37 percent in 1943. The 1944 intercoastal shipments of gasoline were 3 percent larger than those of 1943. Shipments of kerosine were slightly larger in 1944 than in 1943, and shipments of residual fuel oil gained 57 percent over 1943. On the other hand, shipments of distillate fuel oil were 11½ percent less in 1944 than in 1943.

Mineral oils, crude and refined, shipped commercially from Gulf Coast to East Coast ports of the United States, 1943-44, by classes ¹

NATURAL GASOLINE

SUMMARY

Continued expansion of production and demand to record levels were reported by the natural-gasoline industry in 1944. The total output of light products derived from natural gas increased 14 percent over 1943 to 4,201,932 thousand gallons with an estimated value at the plants of \$182,500,000 (24 percent more than in 1943). Although the production of liquefied petroleum gases increased rapidly (29 percent above 1943), the supply was inadequate to meet all demands. The output of cycle plants, other than liquefied gases, was 28 percent higher and natural-gasoline production 3 percent higher than in 1943.

The market for light products remained strong in 1944, reflecting heavy demand for many war purposes. The spot price for 26-70 grade natural gasoline in the Mid-Continent (Group 3) area had advanced to 4.75 cents per gallon in October 1943 and was unchanged throughout 1944. The average price for the year was therefore 4.75 cents, compared with 4.13 cents in 1943.

Stocks of all light products declined from 190,722,000 gallons on January 1, 1944, to 178,584,000 gallons on December 31, owing to depletion of inventories at refineries, particularly on the East coast and in California. Stocks at plants and terminals were little changed.

Exports in 1944—42,696,000 gallons—were 21 percent above 1943 but far below the average of prewar years. Recent shipments have been limited almost entirely to Canada and Mexico.

¹ Data for 1944 are preliminary; detailed statistics with final revisions will be released later.

² Tables compiled by E. M. Seeley, Petroleum Economics Division, Bureau of Mines.

¹ Subject to revision.

² Not available.

³ For comparison with 1940.

⁴ Figures from data compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

⁵ Includes liquefied gases used in chemical manufacturing.

⁶ From independent survey of consumption. See discussion on Liquefied Petroleum Gases at end of this chapter.

Estimated.

PRICES AND MARKET CONDITIONS

The price ceiling on the 26-70 grade of natural gasoline in Oklahoma, originally set at 4.875 cents a gallon by the Office of Price Administration, was revised downward to 4.75 cents, a figure considered more representative of actual realization by producers in the base period—the 60 days prior to October 15, 1941. The spot price coincided with this ceiling during 1944, and ceilings on other light products in tank cars were unchanged except for minor adjustments in a few districts.

On tank-wagon deliveries of commercial grades of liquefied gases, the ceiling price was raised 2 cents per gallon to compensate for higher costs of distribution.

As in 1943, light products entering into the manufacture of such critical war items as aviation gasoline and synthetic rubber were not restricted in price. Influenced primarily by this free market portion

of sales, the average value at the plants of natural gasoline and cycle products is estimated to have increased from 4.4 cents a gallon in 1943 to 4.9 cents in 1944.

Because of diversion of tetraethyl lead and high-octane gasoline components to military production, refiners were unable to maintain the 72-74 octane specification for civilian-grade motor fuel. The requirement was therefore relaxed to 70-74 octane on August 15, 1944, and the price ceiling at refineries and bulk terminals was reduced one-eighth cent per gallon. The average spot price in Oklahoma for this grade of United States motor fuel was 5.96 cents per gallon in 1943 (ceiling, 6.00 cents), and 5.95 cents, the average ceiling price in 1944 (see fig. 1).

FIGURE 1.—Trends in average value of natural gasoline, spot price of gasoline, and stocks of natural gasoline, 1918-44

PRODUCTION

Trends in total output.—The production of crude petroleum increased 11 percent in 1944, and that of natural gasoline and cycle products (except L. P. G.) increased 9 percent to new high levels (see fig. 2). The monthly trend of both series was upward, responding to growing demands of the war economy.

FIGURE 2.—Annual production of natural gasoline and crude petroleum, 1911-44

A small gain (3 percent) restored natural-gasoline output to the approximate level of 1940-41. The output of cycle products and liquefied petroleum gases in 1944 was 76 percent and 66 percent, respectively, greater than in 1941. One large new cycle plant in Louisiana and one in California contributed to the 1944 production.

The total liquid production at natural-gasoline and cycle plants averaged 10.8 million gallons daily in the first quarter of 1944 and 12.2 million gallons in the fourth quarter. The total output of 4,201.9 million gallons equaled 6 percent of the volume of crude petroleum produced in the United States in 1944.

Natural gasoline and cycle products produced in the United States, 1940-44, by States, in thousands of gallons

¹ Subject to revision.

² Estimated.

³ Includes Utah in each year.

⁴ Includes cycle products as follows—1940: 165,690,000 gallons; 1941: 480,354,000 gallons; 1942: 654,864,000 gallons; 1943: 657,846,000 gallons; 1944: 843,024,000 gallons.

California.—The total output of plants increased 11 percent over 1943 to a new record of 771.3 million gallons. Natural-gasoline production was 9 percent larger in 1944 and liquefied petroleum gases 25 percent larger than in 1943. A total of 171 million gallons of light products was produced at Kettleman Hills compared with 143 million in 1943. The Ventura Avenue field ranked second in the State, with an output of 86 million gallons in 1944, and Long Beach third, with 81 million gallons.

Louisiana.—Production from the Erath cycle plant in the Gulf district, which began operations in April, caused the total light products output of the State to gain 61 percent in 1944 to 492.6 million gallons. Louisiana became the third State in volume of production, displacing Oklahoma. The output of cycle products and liquefied petroleum gases was 90 and 106 percent, respectively, above that in 1943. Natural gasoline increased only 5 percent and amounted to 24 percent of total production in 1944, compared with 52 percent in 1941.

Monthly production of natural gasoline and allied products in the United States, 1943-44, by States and districts, in millions of gallons

¹ Subject to revision.

Oklahoma.—The slow decline in total output of recent years appears to have ended in 1944, when 421.8 million gallons of light products were produced, compared with 422.3 million in 1943. Production early in 1944 was below comparable months of 1943, but the daily average for the last quarter of 1.22 million gallons was 2 percent

higher than the comparable 1943 figure. The Osage output of 75 million gallons was 8 million gallons above 1943. Oklahoma City declined 7 million gallons to 53 million in 1944.

Texas.—Total production of 1,870.4 million gallons exceeded the old 1943 record by 14 percent. Increased output over 1943 was reported for all classes of products as follows: Natural gasoline 8 percent, cycle products 9 percent, and liquefied gases 28 percent. All districts gained in 1944, led by the Gulf Coast and the Panhandle. Although productive facilities were added to many plants, the only new plant of large capacity to commence operations in 1944 was in the Wasson field of West Texas.

Natural gasoline and allied products produced and natural gas treated in the United States in 1943-44, by States

¹ A producer operating in more than 1 State is counted but once in arriving at total for United States.

² Subject to revision.

³ Drip gasoline produced in Colorado and Utah included with Wyoming.

⁴ Not available.

Other States.—Arkansas production continued to expand rapidly (33 percent), as more of its available "sour" gas was processed for removal of sulfur and liquid hydrocarbons. The output of the Rocky Mountain States and Kentucky increased moderately, and the small Michigan production was raised 608 percent in 1944. Illinois production was 9 million gallons higher than in 1943 but followed a declining trend after the peak month of October 1943. Recovery of liquefied gases in Illinois gained about 19 million gallons, and natural gasoline declined 10 million gallons.

The only notable declines in output were in Kansas (18 percent) and West Virginia (9 percent). The former was related to the down trend in crude petroleum production and the latter to reduced recovery from the important Charleston gas field.

POSTWAR OUTLOOK

A projection of current information to the end of 1945 suggests the following situation. The effective capacity of the industry to produce will amount to approximately 6,000 million gallons (148 million barrels) per year. Equipment will be available to recover at least 2,200 million gallons of this total in the form of liquefied gases of the pentane and lighter series. Of the remainder, about 3,500 million gallons may be classified as natural gasoline and other unfinished materials and 300 million gallons as other products (chiefly finished gasoline).

Actual production of light products at natural-gasoline and cycle plants in 1941, the prewar peak year, was 3.4 billion gallons, or 43 percent less than the prospective capacity mentioned above. Of this total, refiners used about 2.3 billion gallons; jobbers, exports, and losses took 0.8 billion; and liquefied-gas markets for fuel and chemical manufacturing accounted for about 0.3 billion.

Assuming that refiners will utilize the same quantity of light products in the first postwar year as in 1941, the natural-gasoline industry will have available capacity to produce about 3.7 billion gallons of products for other markets. The demand for liquefied gases for fuel and chemical uses may be expected to absorb 0.9 billion gallons, judging from the rapid growth trend of the recent past. It is estimated that other sales and losses will account for about 1.0 billion gallons.

These figures indicate that the available capacity of the industry may exceed prospective markets by 1.8 billion gallons annually (or 30 percent of total capacity), of which about one-third will be suitable for recovery of liquefied gases and two-thirds for natural gasoline and other products. A material reduction in the rate of petroleum production after the war might reduce the potential excess temporarily to about 1.2 billion gallons.

It therefore appears that a large potential supply of products will be overhanging the market, for which no buyers will be found in the immediate postwar period. Curtailed production and comparatively low prices for most products at the plants are probable, until broader

markets can be developed. As a large section of the industry has the status of a byproduct operation associated with crude petroleum production or natural-gas pipe lines, the response to market conditions will not be uniform. Curtailment of output at many plants may take the form of less complete recovery of available liquids, with attendant increased losses where the residue gas is not utilized for other purposes. Small marginal plants selling in the open market may find their positions seriously impaired. Cycle plants will occupy the strongest position because of low production costs and adaptability of operations.

The price structure will be profoundly influenced, as always, by the level of motor-fuel prices at refineries, which in turn is closely related to the delivered cost of crude petroleum. Reasonably stable crude prices, which seem probable for several years, tend to maintain a floor under prices of all products and may be expected to mitigate the severity and duration of price depressions for the natural group.

With free market conditions, a period of low prices will provide a strong sales stimulus for the industry as a whole because of the many points of close competitive contact with materials from other sources, the costs and price habits of which are often less flexible. Continued rapid expansion in use of liquefied gases for both established and new purposes may be expected to alleviate problems of surplus supply in this section of the industry. The major difficulty appears to be that of obtaining satisfactory markets for natural gasoline and similar broad fractions. This challenges the technical ingenuity of the industry and its resourcefulness in the field of marketing. Processing changes to produce more products suitable for direct marketing to the public, particularly motor fuel, will doubtless play a part, as will an aggressive program of market development.

MARKET DEMAND

The total demand for light products, including liquefied gases sold by petroleum refineries for fuel purposes, increased 14 percent in 1944 to 4,498,704 thousand gallons. The consumption of all major product groups was higher in 1944 than in 1943 by the following percentages: Natural gasoline 3 percent, cycle products 28 percent, and liquefied petroleum gases 31 percent.

Refinery utilization.—Petroleum refineries utilized 2,822,694 thousand gallons of natural gasoline and allied products in 1944, an increase of 10 percent over 1943. Of this total, 65 percent was natural gasoline, 14 percent cycle products, and 21 percent liquefied gases and benzol. The demand for pentanes and butanes at refineries has increased rapidly because of their great value in high-octane gasoline production for the armed forces. Until a few years ago, treatment at refineries of liquids derived from natural gas was generally limited to minor fractionation and direct blending into finished products for sale to consumers. Modern procedure subjects the bulk of these materials to close fractionation or extensive chemical reorganization by synthesis or cracking before they become finished products, as such or by blending.

¹ Not comparable with prior years because relatively more liquefied petroleum gas is included.

² Subject to revision.

"Direct" sales.—Sales of natural gasoline and cycle products to jobbers and retailers continued the decline that has characterized the war period. The urgent demand from refiners to meet their quotas of military gasolines under the war program expanded to record volume in 1944 and tended to further restrict supplies available to distributors. Motor-fuel rationing also may have affected adversely the volume of business available to dealers.

Sales of liquified gases for fuel in 1944 were 9 percent greater than in 1943 in spite of restrictions upon civilian usage and equipment. Essential industrial and military uses were materially higher than in 1943. The growth of normal fuel markets for liquefied gases has been retarded by war needs.

Exports.—Foreign shipments continued at an abnormally low level in 1944, although 21 percent above 1943, reflecting heavy domestic demand and the war-induced scarcity of shipping. Of the total light products exported, 28.2 million gallons were classified as natural gasoline and 14.5 million as liquefied petroleum gases. The total value of exports was \$2,865,827 in 1944 and \$2,168,407 in 1943.

Of the total shipments of 42,696 thousand gallons, the following quantities were distributed to the principal countries of destination: Canada, 34,504 thousand gallons, Mexico, 7,749, and Portugal, 64.

STOCKS

Total stocks of products of the natural-gasoline industry declined during 1944 from 190,722 thousand gallons on January 1 to 178,584 thousand gallons at the year end. The relative stability of stocks throughout the year is indicated by their extreme range of 16,800 thousand gallons compared with 41,874 thousand in 1943.

Reversing the large gain in 1943 (23 million gallons), stocks at refineries declined 13 million gallons. Those at plants and terminals increased to a peak in May 1944 and were drawn down in later months to end the year slightly above the level of January 1, 1944. Stocks at California refineries were reduced 9.5 million gallons during 1944 and those on the East coast 7.7 million gallons to a very low level. Material declines occurred also in Wyoming and the Louisiana Gulf district. Stocks in Texas and Oklahoma rose moderately.

Trends in stocks by grades in 1944 were similar to 1943. Natural gasoline fell 15.7 million gallons; cycle products and liquefied gases rose 2.1 and 1.4 million gallons, respectively.

TECHNOLOGIC DEVELOPMENTS

Cycle plants.—The first cycle plant in California went on stream in June 1944 in the Paloma field. At Erath, La., the largest cycle plant thus far constructed began operating about May 1, almost doubling the rate of light-products production in the State. Enlargements to the Katy, Tex., cycle plant in 1944 and 1945 may increase its capacity above that of the Erath plant.

The more complete cycle plants are verging upon the status of a refinery in that they produce a considerable volume and variety of finished products of high grade. Chemical plants on the Gulf coast are providing a new market for over 5,000 barrels per day of liquefied gases produced at cycle plants.

Yields.—The average yield of all products at natural-gasoline and cycle plants was 1.22 gallons per thousand cubic feet in 1943, unchanged from 1942. Yields declined in eight States in most of which unit recoveries are characteristically low because a large proportion of the gas treated originates in gas fields and is stripped preparatory to entering gas pipelines. Of the six States in which yields increased, five are above the national average in recoveries because most of the gas treated at plants is produced in oil fields. Louisiana is an exception because of the domination of cycle-plant operations in the field of light-products production from natural gas.

Production by processes.—The total number of operating plants in 1943 was 642, a net loss of 25 from 1942, including 19 of the compression type. In all, 21 compression plants were shut down and 2 commenced operating. Eight absorption plants were added to the active list, and 11, of which 6 were in Oklahoma, ceased operations. Two

new cycle plants were put in operation in Texas in 1943. . The indicated decline of 3 in the total number of cycle plants operating results from elimination of 5 small plants that had functioned, chiefly as separators, in condensate-type fields.

Owing to a gain in Texas, the compression plants produced almost 7 percent of the total output in 1943 compared with less than 6 percent in 1942, and absorption plants produced 73 percent compared with 74 percent in 1942. The share of cycle plants was 20 percent in both years, and production by the charcoal method declined to a negligible fraction of 1 percent. Production of liquefied petroleum gases was reported at 191 plants in 1942 and at 204 in 1943.

Vapor pressures.—The average vapor pressure of natural gasoline produced east of California was 20.6 pounds in 1944. This average had risen from a low of 19.3 pounds in 1940 to 21.2 pounds in 1943.

⁴ Includes 167 plants manufacturing liquefied petroleum gases.

⁵ Includes 20 plants manufacturing liquefied petroleum gases.

⁶ Drip gasoline.

Technical trends.—Emphasis continues upon the production at plants of greater quantities and variety of specific products for specific needs—in other words, an increase in the scope of liquid processing at larger, more efficient plants. The resulting increase in plant investment per gallon of output is justified on the basis of the higher unit prices commanded by products that meet rigid specifications than can be realized from the broad, relatively raw fractions.

Absorption pressures currently range from two to five times those in general use before the war, and recovery of butanes is approximately double the old average, approaching 100 percent in the most efficient plants. The recovery of propane is also notably higher at many plants but is still far below the total potential supply because of economic limitations. As only about one-third of the plants in the

natural-gasoline industry are equipped to segregate liquefied gases, this phase of the business appears to be susceptible of significant further development under favorable economic conditions. Rapid expansion in the use of propane for chemical and fuel purposes after the war is anticipated by many in the industry.

Greater plant investment is related chiefly to the heavy equipment required for higher operating pressures, more elaborate facilities for fractionation, synthetic and other chemical processing; and circulation of absorption oil. Storage vessels for products of widely different physical characteristics must also be provided.

Some of the plants associated with pressure maintenance or repressuring in oil fields should occupy a strong position because, among other factors, some of their costs may legitimately be charged to oil-producing operations.

LIQUEFIED PETROLEUM GASES; SALES SURVEY

The percentage rate of gain in annual sales of liquefied petroleum gases declined from 27 percent in 1942 to 15 percent in 1943; however, it turned sharply upward in 1944 when comparative deliveries of 905,600,000 gallons were 34 percent above the 1943 total of 675,233,000 gallons. The 1944 survey of the Bureau of Mines was extended to cover material delivered for synthetic rubber components, and when this additional demand is included the 1944 quantity expands to 1,061,809,000 gallons—a total realized in spite of wartime regulations, equipment and transportation difficulties, and ever-increasing diversions to satisfy the demand for aviation-grade motor fuel and possible because of greatly increased production of liquefied petroleum gases from both old and new plants.

Sales of liquefied petroleum gases in the United States, 1937-44, in thousands of gallons

Year	Butane	Propane	Butane-propane mixtures	Pentane	Total	
					Quantity	Percent of increase over preceding year

¹ Subject to revision. ² Includes material delivered for synthetic rubber components. ³ Without synthetic rubber components for comparison with 1943. ⁴ Not available.

Petroleum refineries, gasoline plants, and cycle plants cooperating in the 1944 survey reported 156,209,000 gallons of liquefied petroleum gases delivered for synthetic rubber components. Most of this material—144,370,000 gallons or 92 percent—was indicated as butane or related gases, and all of it was reported for areas east of California. The above quantity of liquefied petroleum gases delivered for the manufacture of synthetic rubber is below the 1944 total released by

the Petroleum Administration for War as estimated from its industry survey for the same areas—districts 1 to 4. The Bureau of Mines survey was based on actual deliveries; furthermore, reporting companies were asked to limit items to liquefied gases, whereas the industry survey covered material in a liquid as well as a gaseous state.

Omitting sales of material reported for synthetic rubber components so that 1943 and 1944 items will be on a comparative basis, all principal uses of liquefied petroleum gases showed greater percentage gains in 1944 than in 1943, except the demand for industrial fuel, which expanded at a lesser rate than in 1943, and "All other uses," which registered a loss in 1944. The percentage increases in 1944 were quite different from those in 1943, when the demand for industrial fuel showed a larger gain and other principal uses smaller rates of expansion than in 1942.

Sales of liquefied petroleum gases for domestic use increased by 29 percent from 339,380,000 gallons in 1943 to 438,552,000 in 1944. The important gain in 1944 indicates that the downward trend in the annual expansion rate (65 percent gain in 1941, 36 percent in 1942, and 13 percent in 1943) has been arrested and that distributors are finding ways to overcome appliance and transportation difficulties in order to market a growing production. Manufactured-gas companies are using an ever larger amount of liquefied petroleum gases for direct distribution or for stand-by gas, and they increased their purchases by 27 percent from 37,519,000 gallons in 1943 to 47,768,000 in 1944. Deliveries of liquefied petroleum gases for industrial fuel rose from 149,429,000 gallons in 1943 to 163,036,000 in 1944—a 9-percent gain in contrast to a 31-percent expansion in 1943 over 1942. The lower rate of increase in 1944 reflects equipment and transportation difficulties and also the diversion of butane for other purposes.

A greatly stepped-up use of liquefied petroleum gases as raw material for chemical manufacturing is indicated in sales of 151,985,000 gallons for this purpose in 1944—a quantity nearly triple the 1943 demand of 55,356,000 gallons. Part of this growth reflects expansion under war conditions; however, some of it is due to more complete reporting of this demand in 1944 than in 1943. Liquefied petroleum gases delivered for internal-combustion-engine fuel increased from 87,834,000 gallons in 1943 to 101,760,000 in 1944—a 16-percent gain compared with a 7-percent increment in 1943 over 1942.

Restrictions on butane equipment and its diversion for the manufacture of synthetic rubber and high-octane motor fuel have tended to lower the relative proportion marketed for fuel purposes. The butane item in the annual sales has dropped steadily from 24 percent of the total in 1941 to 15 percent in 1944, and most of this decline occurred in 1944 when nonfuel demands for butane approached peak levels. The fuel load has shifted to propane and butane-propane mixtures, and relative proportions for these gases have increased in recent years. The share of propane in the annual total has mounted from 27 percent in 1941 to 36 percent in 1944, whereas "mixtures" have expanded from 47 to 50 percent of the total in the same period. The rise in the relative proportions for these gases during the several years has not been constant, however, as the percentage share for propane declined in 1942, when there was an unusual increase in deliveries of butane-propane mixtures. Then the percentage of "mixtures" in the total dropped in 1943, to be followed by a gain in 1944. Pen-

tane reported in the annual survey has made up less than 1 percent of the total in recent years, so this "gas" was dropped from the 1944 schedule as being relatively unimportant. Furthermore, some authorities have contended that, strictly speaking, pentane should not be included as a liquefied petroleum gas.

Deliveries of butane declined 5 percent, from 140,122,000 gallons in 1943 to 132,870,000 in 1944, as restrictions governing certain uses were enforced and larger quantities were diverted for raw material to the synthetic rubber and chemical industries. Shrinkage in the consumption of butane as a domestic fuel, first noticed in 1943 with a 2-percent decline, was strongly evident in 1944, when sales of 27,565,000 gallons were 38 percent below the 1943 total of 44,255,000 gallons. The use of butane as motor fuel, which is greatly limited under present conditions, has declined from 14,870,000 gallons in 1942 to 9,895,000 in 1943 and to 4,030,000 in 1944. Sales of butane for industrial fuel, which showed some expansion in 1942 and 1943, declined by 6 percent from 56,143,000 gallons in 1943 to 52,890,000 in 1944, although equipment for the use of industrial plants is not limited. Manufactured-gas companies, under no restrictions regarding equipment for the handling of butane and endeavoring to take care of more customers and heavier service loads, purchased 24,900,000 gallons of butane in 1944 or 14 percent over 1943 requirements of 21,829,000 gallons. The use of butane as raw material in the manufacture of chemicals showed a strong upward trend in 1944, and the demand of 23,475,000 gallons was far above the 1943 total of 7,972,000 gallons.

Changes in the principal demands for butane stand out when reviewed with respect to the percentage of total sales. Butane reported for domestic fuel has declined from 35 percent of all demands in 1942 to 32 percent in 1943 and down sharply to 21 percent in 1944. The proportion of butane consumed as motor fuel has shown a similar downward trend from 12 percent of all requirements in 1942 to 3 percent in 1944. Butane credited as industrial fuel has remained fairly constant at about 40 percent of all principal uses in recent years, but the percentage share sold to manufactured-gas companies of 19 percent in 1944 is double the 1942 proportion. The percentage of butane sales reported for chemical raw material mounted sharply from 6 percent in 1943 to 18 percent of the 1944 total.

That a large share of the fuel load formerly carried by butane has been shifted to propane under present conditions is evident in the 48-percent gain in sales of propane from 218,273,000 gallons in 1943 to 323,848,000 in 1944. All principal uses of propane showed outstanding gains in 1944. Deliveries for domestic consumption increased by 34 percent from 124,670,000 gallons in 1943 to 166,947,000 in 1944. It should be noticed, however, that as propane is diverted to other uses, the share credited to household consumption has declined from 75 percent of the total demand in 1942 to 57 percent in 1943 and then to 52 percent in 1944. Industrial plants have turned strongly to propane for fuel in place of butane, and the demand has expanded from 20,601,000 gallons in 1942 to 73,698,000 in 1943 and to 90,674,000 in 1944. Manufacturing plants again used more propane than butane in 1944 as they did for the first time in 1943. Furthermore, propane delivered for industrial fuel made up 28 percent of the total for all uses in 1944 against a 34-percent share in 1943. Requirements for propane by

manufactured-gas companies increased from 8,117,000 gallons in 1943 to 17,103,000 in 1944; however, the 1944 item for this particular use was still below the corresponding demand for butane. Sales of propane for raw material to chemical manufacturing plants jumped from 4,455,000 gallons in 1943 to 40,666,000 in 1944; however, it is believed that the 1943 demand was not fully reported. Propane used as fuel in internal-combustion engines advanced from 4,592,000 gallons in 1943 to 6,650,000 in 1944, and the latter quantity is above the corresponding butane item for the first time in 1944.

Deliveries of butane-propane mixtures in 1943 were little above the 1942 total; but in 1944 when there were difficulties in obtaining enough butane for all purposes there was a general turning to both propane and to butane-propane mixtures for fuel and for raw material in the chemical industry. Reported sales of "mixtures" increased by 44 percent from 312,683,000 gallons in 1943 to 448,882,000 in 1944, and the expansion was limited largely to domestic-fuel and chemical-manufacturing demands. More than half (54 percent in both 1943 and 1944) of the butane-propane mixtures is sold for domestic fuel, and requirements increased by 44 percent from 169,818,000 gallons in 1943 to 244,040,000 in 1944. "Mixtures" delivered as raw material to chemical plants made up 20 percent of the 1944 total (13 percent in 1943), and the quantity more than doubled from 39,584,000 gallons in 1943 to 87,844,000 in 1944. Liquefied petroleum gases used as fuel in internal-combustion engines are usually a mixture of butane and propane, and the demand has expanded steadily in spite of restrictions. "Mixtures" delivered for engine fuel constituted 20 percent of all demands in 1944, and the total of 91,080,000 gallons was 24 percent over 1943 deliveries of 73,344,000 gallons. Industrial plants turned strongly to propane for fuel in 1943 and 1944, and as a result their purchases of butane-propane mixtures remained at the same level—19,472,000 gallons in 1944 and 19,474,000 in 1943. Manufactured-gas companies have increased their demand for both butane and propane in recent years; however, their requirements for "mixtures" have dropped from 7,532,000 gallons in 1943 to 5,765,000 in 1944.

¹ Subject to revision.

² Includes material delivered for synthetic rubber components.

³ Without synthetic rubber components for comparison with 1943.

⁴ Not available.

The relative proportions of the different gases delivered for the principal uses have varied greatly in the war years. Sales of butane for domestic fuel have declined from 15 percent of the total in 1941 to 6 percent in 1944—a shrinkage due to present restrictions and the expanding requirements for butane as a raw material. The relative amount of propane in the domestic-use item has also declined, dropping from 44 percent in 1941 to 37 percent in 1943; however, there was a slight upward turn in the quantity to 38 percent of the total demand in 1944. The declining share of the household fuel formerly credited to butane and propane has been shifted to butane-propane mixtures, and these have increased from 40 percent of the domestic total in 1941 to 56 percent in 1944.

Relatively more butane and propane and less butane-propane mixtures are sold to manufactured-gas companies at present than in former times; however, the percentage shares show fluctuations from year to year. The butane proportion dropped from 48 percent in 1941 to 40 percent in 1942 and then rose to 58 percent in 1943. It did not remain at this high level, receding to a 52-percent share in 1944. The percentage of propane delivered to manufactured-gas companies dipped from 27 percent in 1941 to 16 percent in 1942 and then turned upward to a 22-percent share in 1943 and 36 percent in

1944. The relative quantity of butane-propane mixtures credited to gas companies has diminished steadily from the unusually high proportion of 45 percent in 1942 to 12 percent of the total in 1944.

Liquefied petroleum gases used for industrial fuel have shifted strongly to propane and away from both butane and butane-propane mixtures in recent years. The propane proportion has "sky-rocketed" from about an 18-percent share in 1941 and 1942 to 49 percent of the total in 1943 and 56 percent in 1944. The butane percentage for industrial fuel has not dropped as drastically as that for "mixtures." The butane share has declined from 47 percent of the demand in 1941 to 32 percent in 1944, whereas that for butane-propane mixtures has shrunk from 36 percent of total requirements to 12 percent in the same interval.

Relatively more butane-propane mixtures are reported for chemical raw material than the other liquefied petroleum gases; however, the percentage for "mixtures" has declined sharply from 89 percent of the total in 1941 to 58 percent in 1944. Butane delivered to chemical plants has increased from less than 1 percent of the total in 1941 to 15 percent in 1944, but the proportion of propane has advanced intermittently from 4 percent of the demand in 1941 to 27 percent in 1944. Pentane satisfied about 7 percent of the chemical demand for liquefied petroleum gases from 1941 to 1943.

Liquefied petroleum gases used as fuel in internal-combustion engines have been predominantly butane-propane mixtures, and the relative proportion has increased as the demand for butane for raw material has mounted. The percentage of "mixtures" for this particular use has advanced from 70 percent of the item in 1941 to 90 percent in 1944, while the butane total has dropped from 28 percent of the requirements in 1941 to 4 percent in 1944. Very little propane is sold for internal-combustion-engine fuel, yet the quantity has increased from 2 percent of the total in 1941 to 7 percent in 1944.

The American Gas Association has reviewed the distribution of liquefied petroleum gases by manufactured-gas companies in 1944 as follows:

At the end of 1944, liquefied petroleum gas was being delivered through mains to consumers in 224 communities in 32 States by 101 companies supplying 94,660 consumers.

Butane-air gas with heating value ranging from 520 to 1,600 B. t. u. per cu. ft. was supplied to 166 communities in 31 States. A mixture of undiluted butane and propane gas with a heating value of 2,800 to 3,000 B. t. u. per cu. ft. was supplied to 18 communities in Arizona, California and New Mexico. Undiluted propane gas with a heating value of 2,550 B. t. u. per cu. ft. was supplied to 40 communities in Maryland, Minnesota, New Jersey, North Dakota, Virginia and Wisconsin.

Partly estimated totals covering sales of liquefied petroleum gases in the Pacific Coast area—California, Oregon, Washington, Arizona, and Nevada—indicate a demand of 168,566,000 gallons in 1944, a 23-percent gain over 1943 deliveries of 136,601,000 gallons. Liquefied petroleum gases marketed on the Pacific coast constituted 19 percent of the national total in 1944 and 20 percent in 1943. Distributors in "all other areas" reported sales of 737,034,000 gallons of liquefied petroleum gases in 1944 compared with a market for 538,632,000 in 1943—an increase of 37 percent. An additional quantity of 156,209,000 gallons of liquefied petroleum gases was diverted to plants east of California in 1944 for the manufacture of synthetic rubber.

SUMMARY

The demand for carbon black reached unprecedented proportions in 1944, exceeding production by 135,570,000 pounds. As a result, producers' stocks were reduced to 69,243,000 pounds on December 31, the lowest level since 1928. Further drafts upon these stocks in the early months of 1945 depleted them almost to the vanishing point in spite of an increasing production rate.

The major factor in demand was the rapid rise of synthetic rubber production and processing that followed the development of successful techniques under the compulsion of war necessity. This achievement in production made possible a record consumption in 1944 of rubber which contributed vitally to the prosecution of the war in a growing variety of applications. The effect upon the demand for carbon black was magnified by the peculiar properties of synthetics, which require for highest efficiency much more carbon black per pound than does natural rubber. Deliveries to rubber companies were 56 percent above 1943 and accounted for 95 percent of total domestic sales. They amounted to over 950 pounds per ton of rubber of all types consumed in 1944.

CURRENT AND POSTWAR OUTLOOK

Although the rate of production of carbon black of rubber grades in the first quarter of 1945 was about 31 percent higher than a year earlier, the consistent excess of demand over production caused the War Production Board to take emergency action to curtail consumption increase production. In February the permissible quantity of carbon black in rubber was reduced an average of about 10 percent below general practice to conserve several million pounds a month. Arrangements were made in March to increase the output of some active plants by enrichment of gas with propane and gasoline. Higher price ceilings were allowed on added production of channel and furnace black under emergency high-cost conditions. Other steps, including assignment of top priorities on materials and manpower, were taken to expand productive capacity as soon as possible.

The military victory in Europe was followed in May 1945 by a cut-back of rubber requirements for the Army. This development and the rapid rise in carbon-black output brought supply and demand into close balance for the first time in about 2 years. Projected requirements for synthetic rubber of 1 million long tons in 1945 and 1.2 million in 1946, as announced by the Rubber Reserve Company, indicate that little increase above current rates of production (296,045 long tons in the first 4 months of 1945) will be required. On the other hand, further large gains in carbon-black production are scheduled for later months in 1945 as new facilities come into operation which may raise the rate above 110 million pounds per month. It may be expected, therefore, that the supply of carbon black through 1946 will suffice for domestic requirements for rubber and other established uses and for a material increase in exports over the monthly average in 1944. The emergency restrictions placed in February upon carbon black "loading" in rubber, as mentioned above, were canceled early in June.

From a longer range view, many conditions that will influence the demand for carbon black during the 5 years following the war are not predictable. Some of the fundamentals that have been widely studied and discussed and an appraisal of the rapid developments of the past

2 years may serve as the basis for a speculative analysis with some merit.

The annual world absorption of crude rubber in the period 1936-40 averaged almost 1.1 million long tons, of which the United States took 60 percent in 1940. Sales of carbon black in this period by United States manufacturers, to rubber companies and for export, averaged approximately 415 pounds per ton of rubber absorbed. As recent practice has been to add more carbon black per ton of natural rubber compounded, an average of 460 pounds per ton (the 1939-40 experience) is considered more representative of present and prospective conditions.

A number of estimates of postwar rubber consumption have been published which indicate that about 1.5 million tons per year will be used, exclusive of reclaimed rubber. This quantity approximates a projection of the long term trend in rubber consumption and therefore assumes a continuation of growth at a rate comparable with the average in the 1925-40 period.

In order to estimate the amount of carbon black to be used with rubber, some measure of the proportion of synthetic to natural types that may be compounded is necessary. Although it is recognized that a high factor of error is inherent in any forecast of the synthetic rubber industry, the following assumptions appear reasonable on the basis of fragmentary information at present available. In making them, emphasis has been placed upon the probable economic and strategic position of synthetics. No attempt is made to appraise variants that may be introduced by future national or international policies. In the first year following liberation of the rubber-producing areas, consumption of about 800,000 tons of synthetic rubber is probable, the total declining in the following 4 years to a rate of about 400,000 tons, to average 600,000 tons for the period.

Technical advance is steadily improving the cost and quality factors upon which synthetic rubber may depend in postwar competitive markets. In May 1944 the most efficient plant produced GR-S (Buna-S) rubber at a cost of 14 cents a pound, including plant amortization over a 10-year period,¹ and trade sources indicate that a cost of about 10 cents may be possible under peacetime conditions. Important new techniques, such as those involving continuous polymerization of rubber and the addition of carbon black to liquid latex before coagulation, accomplish cost reductions and improve the quality of the product. The extent to which ingenuity may alter the economics of synthetic rubber in a given period can only be conjectured. However, a rather effective ceiling has already been placed upon the future delivered cost of natural rubber, primarily by the development of buna type synthetic rubber. The butyl type is recognized as superior to natural rubber for some special purposes, notably in inner tubes, and will therefore be an important member of the future rubber family.

With the use of 950 pounds of carbon black per long ton of synthetic rubber and 460 pounds per ton of natural, the demand for black in rubber (including 100 million pounds yearly estimated for use in reclaimed) would be about 1,182 million pounds in the first postwar year and average 1,084 million pounds in the 5-year period. To the extent that foreign production of carbon black increases, the demand

¹ U. S. Tariff Commission, Report 6, War Changes in Industry Series, p. 81.

from United States sources will be lessened. On the other hand, a larger consumption of rubber than is projected above would require more carbon black. It must be emphasized that the potential influence of technical advances and Government policy upon future events in this industry is very great and inscrutable. The above figures result from an attempt to reconcile probabilities that appear to be logical outgrowths of the current situation.

It is estimated that consumption of carbon black for purposes other than rubber compounding will average 56 million pounds per year, trending upward from about 52 million in the first postwar year.

An average annual consumption of carbon black for all purposes of 1,140 million pounds is thus indicated for the 5 years succeeding the war, about 1,234 million pounds being needed in the first year and smaller amounts thereafter as more natural rubber enters the trade.

It is anticipated that the total productive capacity of the carbon-black industry in the United States at the end of 1945 will approximate 1,450 million pounds per year, of which about 200 million pounds will represent Government-owned channel-plant facilities. An additional indeterminate portion of total capacity will fall into the emergency high-cost category, supplying the swollen demands of war but destined to cease production upon the return of normal competitive conditions. The ultimate disposition of the Government plants will of course affect the trade position of commercial plants. Of greater moment, however, to the delineation of the postwar economic climate within the industry will be the extent of direct competition between blacks of the channel and furnace types.

Information currently available indicates that the return to large use of natural rubber will increase the demand for channel black, although its fields of application may be narrowed (as compared with the prewar period) by the availability of suitable furnace blacks at competitive costs. Higher future costs for gas at channel plants, which appear to be in prospect, would operate to the competitive disadvantage of these plants because of the low-product yields. The principal furnace grades may therefore have the advantage of lower unit production costs which would encourage their substitution for channel blacks, on a price basis, for many purposes for which the two types of black are more or less interchangeable on a quality basis.

PRODUCTION

By States.—Texas production increased 23 percent in 1944 to a new record of 501,162,000 pounds, owing to gains of 16 percent in the Panhandle, where more gas became available to carbon-black plants, and 61 percent in other parts of the State. Texas' share of the total United States output, however, declined to 62 percent, prolonging a trend that has persisted since 1938, when the State produced 87 percent of the total.

An expansion of 46 percent over 1943 in Louisiana raised production to 160,019,000 pounds, exceeding the old 1924 record by 11 percent. Oklahoma production of 53,887,000 pounds was 72 percent above 1943, and output of the California-Kansas-New Mexico group gained 93 percent in 1944 despite a decline in California.

Methods and yields.—The average yield of all carbon blacks increased to 2.20 pounds per thousand cubic feet of gas burned in 1944 from

¹ In counting the total number of producers reporting, a producer operating in more than 1 State, district, or county is counted but once.

² Includes carbon black made from liquid hydrocarbons.

1.88 pounds in 1943, influenced by further rapid gains in furnace-plant operations. Higher yields were indicated in all districts.

Furnace blacks constituted 48 percent of total production in 1944 and 36 percent in 1943. Early in 1945, about 50 percent of the output of furnace black was of the semireinforcing grade, over 30 percent high modulus, and the balance thermal.

Furnace plants in 1944 consumed 40,444 million cubic feet of natural gas and over 10 million gallons of liquid hydrocarbons. The yields by furnace processes, expressed in pounds per thousand cubic feet of gas, vary from 3 to 16 pounds, depending upon the quality of black produced and the proportion of gas to liquids processed. No specific data are available to measure the quantity of black recovered from oil, and therefore an expression of average yield on the basis of gas input alone cannot accurately reflect the efficiency of the process. It has been stated, however, that by furnace methods 25 percent or more of the carbon in natural gas may be recovered in the form of carbon black.² This indicates at least five times the efficiency of the channel method.

The remainder of the total output, obtained by contact processes, declined to 52 percent in 1944 from 64 percent in 1943. Of the total contact-type production in 1944, almost 80 percent was of easy-processing grade, about 10 percent medium-processing, 3 percent hard-processing, and the remainder "other than rubber" grades. The yield of contact blacks averaged 1.32 pounds per thousand cubic feet of natural gas in 1944 and 1.30 pounds in 1943.

Number and capacity of plants.—Two new plants began production in 1944 as follows:

Continental Carbon Co.—furnace type—at Sunray, Tex.

Phillips Petroleum Co.—furnace type—at Borger, Tex.

The channel plant at Sayre, Okla., did not produce in 1944. It was dismantled and sold. In Louisiana the "Special" contact-type

² Miller, Benjamin, *Postwar Chemical Uses of Natural Gas*: Oil Weekly, Apr. 30, 1945, p. 50.

plant near Bourland was dismantled and the channel plant at Bastrop discontinued operation on November 30, 1944. The roller-type plant at Ryus, Kans., was shut down during 1944.

As a result of these changes, the number of operating plants on December 31, 1944, was reduced to 52 from 54 a year earlier.

In 1944 and the first quarter of 1945, new facilities for production were completed and placed in operation at five new plants and nine producing plants whose capacities were increased. These projects added 146,174,000 pounds to the industry's annual productive ability.

The daily capacity of all plants was increased from 2,166,713 pounds at the end of 1943 to 2,585,416 pounds on December 31, 1944 (19 percent). The ratio of production to total capacity at the year end was 85 percent for 1944 and 75 percent for 1943.

The capacity of contact-type plants totaled 1,344,064 pounds daily on December 31, 1943, and 1,347,710 pounds on December 31, 1944, an insignificant change. Furnace-plant capacity expanded in the same period from 822,649 to 1,237,706 pounds or 50 percent.

Producers.—The Phillips Petroleum Co. was added to the 1944 list of producers. Two or three additional companies using high-yield processes are expected to enter the field in 1945.

DEMAND

Total deliveries.—Producers delivered 937,430,000 pounds of carbon black of all grades in 1944, or 49 percent more than in 1943 and more than double the 1942 total. Miscellaneous users took less black in 1944, but sales to all other domestic trades and for export increased (see fig. 2). Rubber-grade channel blacks were placed under allocation control in July 1944 by the War Production Board, and thereafter rubber-grade blacks were purchased by the Defense Supplies Corporation and resold to rubber companies.

Domestic demand.—Deliveries of 780,478,000 pounds to domestic consumers were 49 percent above the former record of 1943. Demand from rubber companies was more dominant than ever before, absorbing 738,029,000 pounds or 95 percent of total domestic sales compared with 90 percent in 1943.

Sales for rubber manufacture averaged about 70 million pounds per month in the first three quarters of 1944 but jumped to over 90 million in November and remained above 80 million for several succeeding months. Probably this high rate of sales exceeded for a brief period the actual rate of consumption.

Use of synthetic rubber on a large scale has not only accentuated the total demand for carbon black but has caused radical shifts in the relative importance of the various rubber grades. The rapid advance of furnace-type blacks is well-known. The particle sizes in these blacks range larger than in the channel types. Trade reports indicate that current trends are toward the use of more furnace grades of relatively fine texture, particularly the semireinforcing blacks. Among the channel blacks, increasing emphasis has been placed upon easy-processing grades at the expense of the hard grades whose particle size is extremely small. These two preferred types appear to cover the widest area of application of carbon blacks in synthetic rubber, that forms a common meeting ground for furnace and channel blacks, in which they supplement each other and in some degree are interchangeable in practice.

FIGURE 2.—Production and consumption of carbon black, 1933-44. Production in "Texas other than Panhandle" included in "Other States," 1933-35.

Ink companies purchased 24,479,000 pounds of carbon black in 1944, an increase of 4 percent over 1943. According to the Bureau of Foreign and Domestic Commerce, the apparent total consumption of newsprint in the United States was 3,243,000 short tons in 1944 compared with the revised total of 3,627,000 tons in 1943. Disregarding changes in stocks in the hands of consumers, the use of carbon black by ink companies has increased from 5.58 pounds per ton of newsprint consumed in 1939 to 7.55 pounds in 1944.

Demand from paint companies increased 35 percent over 1943 to 5,315,000 pounds. The tremendous volume of naval and merchant ship construction in 1944 required great quantities of gray and other dark paints, which probably exerted an important influence on the carbon-black needs of paint manufacturers.

Sales to miscellaneous industries declined sharply (46 percent) in 1944 to 12,655,000 pounds. This contraction of business is thought to have been chiefly the result of allocation restrictions upon non-essential uses of black, with concurrent reduction of consumers' inventories. Some easing of these conditions is probable in 1945.

*Exports and imports.*³—A 3-year decline in exports was reversed in 1944, as shipments of 156,951,963 pounds were 50 percent above 1943. The largest gains were to the United Kingdom, Canada, and the Union of South Africa, which with India were the four largest importers of carbon black. Together they took 84 percent of total United States exports. Deliveries to the U. S. S. R., Sweden, Australia, and New Zealand were sharply higher, and smaller amounts were taken in 1944 by Spain, Brazil, and several other Latin-American countries whose receipts had increased during the war.

¹ United Kingdom of Great Britain and Northern Ireland.

Shipments were heavy in March and April and in the last quarter when they averaged over 15 million pounds monthly.

Carbon black exported in 1944 was valued at an average of 4.77 cents a pound compared with 4.60 cents in 1943 and the low point of recent years of 4.36 cents in 1939.

³ Figures on exports and imports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Exports from the Galveston customs district more than doubled in 1944, and material gains were reported by the Michigan, New Orleans, and Georgia districts. The comparatively small business through the Los Angeles, El Paso, and Philadelphia districts declined.

Imports of "gas black and carbon black" from Canada continued the upward trend of recent years, amounting to 267,158 pounds valued at \$26,288 in 1944, or 28 and 26 percent, respectively, above 1943. Imports of acetylene black, also received from Canada, increased 82 percent over 1943 to 8,574,693 pounds valued at \$841,483 (9.81 cents a pound) compared with \$381,204 (9.75 cents a pound) in 1943. This material is widely used in the manufacture of dry-cell batteries because of its electrical conductivity.

STOCKS

For the first time in the chapter of this series the stocks of carbon black are segregated into the contact and furnace types. The contact blacks in producers' hands were reduced by urgent demand from 196,913,000 pounds on December 31, 1943, to 58,036,000 pounds at the end of 1944 and fell still further early in 1945.

The very small stock of furnace black on December 31, 1943 (8,302,000 pounds), was built up to 11,207,000 pounds on December 31, 1944, indicating that furnace-black production kept pace with the rapidly growing demand. These stocks, however, had totaled about 18 million pounds in October 1944 and were drawn down, in succeeding months, to a level approximating that of a year earlier.

PRICES AND VALUES

Although price ceilings set by the Office of Price Administration were unchanged in 1944, the average value of carbon black at the plants increased to 3.67 cents a pound from 3.41 cents in 1943. The explanation of the increase is to be found in the rapid gain in output of some furnace grades which sell at higher than average prices.

Continuing pressure for a greater output of channel black caused the Office of Price Administration in March 1945 to raise the price ceiling on added production of rubber grades of channel black obtained under emergency high-cost conditions.

ASPHALT AND RELATED BITUMENS

SUMMARY

In spite of low activity in new highway construction, maintenance and repair work on the existing highways and Government purchases for camps and airfields raised the indicated demand for petroleum asphalt from 6,631,839 short tons in 1943 to 6,944,371 tons in 1944. To meet an increase of 312,532 tons in domestic demand and of 24,413 tons in export demand, petroleum refineries increased their output 239,400 tons over 1943, and imports of petroleum and lake asphalt increased 8,145 tons. To meet the difference of 89,400 tons between increased demand and increased new supply, stocks of asphalt held at refineries increased only 62,900 tons during 1944, compared with an increase of 152,300 tons during 1943.

Domestic demand for native asphalts and bitumens was 12 percent lower than in 1943. Sales of gilsonite were 3 percent less than in 1943, and sales of bituminous rock declined 11 percent.

NATIVE ASPHALT AND BITUMENS

Bituminous rock.—Decreased road-building activity in 1944, partly offset by increased maintenance and repair, resulted in a decline in sales of bituminous rock from 835,648 short tons valued at \$3,096,753 in 1943 to 740,454 tons valued at \$2,771,925 in 1944. The decline was greatest west of the Mississippi River. Sales by producers in Texas and Oklahoma decreased from 600,545 tons valued at \$1,673,689 in 1943 to 479,745 tons valued at \$1,214,329 in 1944. Smaller sales of rock asphalt were made in California and Utah, but larger sales in Missouri. In Kentucky and Alabama, however, producers increased their sales of rock asphalt from 185,723 tons valued at \$1,093,981 in 1943 to 226,190 tons valued at \$1,315,234 in 1944.

Gilsonite and wurtzilite.—A slight decline in tonnage of gilsonite sold by producers in Utah occurred—from 50,446 short tons valued at \$1,188,485 in 1943 to 49,051 tons valued at \$918,480 in 1944. The

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

average sales price per ton at the mine or railhead decreased from \$23.56 in 1943 to \$18.73 in 1944.

Sales of wurtzilite produced in Utah decreased from 41 short tons valued at \$3,250 in 1943 to 11 tons valued at \$874.

Exports.—The tonnage of natural asphalt, unmanufactured, exported from the United States increased from 34,796 short tons in 1943 to 37,210 tons in 1944. The value of these exports, however, decreased from \$819,355 to \$729,765. Although a smaller tonnage of natural asphalt was exported to North American countries and to western Europe than in 1943, larger shipments were made in 1944 to Australia, New Zealand, British India, Saudi Arabia, Madagascar, and the Union of South Africa.

MANUFACTURED OR PETROLEUM ASPHALT

Production.—Production of asphalt by petroleum refineries in the United States increased 3½ percent from 1943. The principal gains in tonnage made were in the East Coast district, in the Rocky Mountain district, in California, and in Louisiana and Arkansas Inland. Proportionally, however, the Rocky Mountain district had the highest increase, followed by the East Coast district, and by Arkansas and Louisiana Inland. In contrast to the national increase, less asphalt was manufactured in central United States, notably the Louisiana Gulf Coast, Texas Inland, Oklahoma-Kansas-Missouri, and Texas Gulf Coast. The greatest decreases, both in tonnage and in proportion, were in the Louisiana Gulf Coast and Texas Inland.

Stocks.—Stocks of petroleum asphalt held at refineries were 11 percent higher on December 31, 1944, than on December 31, 1943. The most marked increases in inventories were in the Oklahoma-Kansas-Missouri district, the East Coast district, the Arkansas-Louisiana

Inland district, and the Appalachian district. In contrast, inventories in Texas Inland, the Texas Gulf Coast, and the Louisiana Gulf Coast were lower at the end of 1944 than at the end of 1943.

Sales.—Sales of petroleum asphalt by refineries to domestic consumers in the United States decreased 2 percent in quantity but 4 percent in value from 1943 to 1944. The average value at the refinery decreased from \$11.43 per short ton in 1943 to \$11.24 in 1944.

Of the total sold, 10.6 percent was manufactured from foreign petroleum (imported chiefly from Venezuela, Colombia, and Mexico) in 1944 compared with 4 percent in 1943. Although runs of foreign crude to stills increased 254 percent from 1943 to 1944, sales of petroleum asphalt from this source increased only 137 percent. Of the foreign crude processed, 14 percent (revised figure) was converted into asphalt in 1943 but only 9 percent in 1944. East Coast refineries sold 99 percent of the total asphalt made from foreign crude in 1944 compared with 71 percent in 1943. Gulf Coast refineries of Louisiana supplied the small remainder.

Highway and street construction and airport-runway surfacing (in the form of paving asphalt, paving flux, cut-back asphalts, and asphalt emulsions) used 71 percent (revised figure) of the total asphalt sold to domestic consumers by petroleum refineries in 1943 and 67 percent in 1944. Street and road contracts exceeding \$25,000, according to

Engineering News-Record, showed a decrease of 14 percent in value—from 227.2 million dollars in 1943 to 195.7 million dollars in 1944—and of 16 percent in indicated volume if the values are adjusted by the Engineering News-Record index of construction costs. The decreases were greatest in the 10 Southeastern States and Louisiana, in the Middle Atlantic States, and in New England. They were least in the 5 States lying between the Ohio River and the Great Lakes and in the 14 States lying west of the Mississippi River and Rocky Mountains.

Although less new road construction was done in 1944, maintenance operations were at a high level. In consequence, sales of paving asphalt used for high-type surfacing declined only 5 percent—from 1,982,457 tons in 1943 to 1,889,966 in 1944. Sales of cut-back asphalts suitable for surfacing lighter-type highways were 7 percent lower in 1944 than in 1943. The popularity of medium-curing cut-backs continued to increase; 3 percent more of this type of cut-back was sold in 1944 than in 1943, but sales of rapid-curing cut-backs decreased 21 percent.

Less emulsified asphalt was sold in 1944 than in 1943. Petroleum refineries sold 107,954 short tons (25,436,068 gallons) valued at \$1,220,177 in 1943 and 97,389 tons (22,946,747 gallons) valued at \$1,113,781 in 1944; in addition, 74,743,426 gallons valued at \$7,003,989 in 1943 (revised figures) and 65,726,027 gallons valued at \$5,970,053 in 1944 were sold by major industrial companies that purchased asphalt from petroleum refineries and manufactured it into emulsions. Accordingly, total known sales of emulsified asphalts and fluxes decreased 11.5 percent in quantity—from 100,179,494 gallons in 1943 to 88,672,774 gallons in 1944—and 14 percent in value—from \$8,224,166 to \$7,083,834.

Roofing manufacture made the second-largest demand for asphalt, absorbing 24 percent of the total sales to domestic consumers in 1943 and 26 percent in 1944. Although shipments of prepared roofing reported to the Bureau of the Census decreased 0.4 percent—from 48,892,000 squares in 1943 to 48,691,000 squares in 1944—domestic

sales of roofing asphalt and roofing flux combined increased 5.6 percent—from 1,670,465 short tons in 1943 to 1,763,552 tons in 1944. These figures do not include roofing asphalt and flux consumed by the companies in factories of prepared roofing owned by themselves or by affiliated companies.

DOMESTIC DEMAND

The indicated average monthly domestic demand for petroleum asphalt (including small quantities of imported lake asphalt and grahamite) was 5 percent larger in 1944 than in 1943, increasing from 552,653 to 578,698 tons.

In order to cover the most recent developments, the long-time trend of monthly asphalt demand has been revised to include 1908 to 1944. The effect of including the last 4 years (which were characterized by extremely high demand) has been to raise the general level of the trend for recent years and to lower the relation between the actual demand for those years and the expected demand according to the trend. This is illustrated by the following table, which shows the relation between the actual average monthly demand from 1925 to 1944 and the expected monthly demand for that period. This comparison indicates that the 5 years 1940-44 have been characterized by rising demand for asphalt, except for 1942, and that the upward trend had shown no sign of downturn to the end of 1944.

In terms of the revised long-term trend, the indicated demand was 38 percent above the expected demand for 1943 and 40 percent above that for 1944; that is, if the national demand had continued the average rate of growth it manifested from 1908 to 1944, it would have averaged 400,949 tons a month in 1943 and 412,072 tons a month in 1944. If these averages are used as a standard of comparison the indicated demand of 552,653 tons in 1943 was 138 percent of the expected demand (400,949 tons), and the indicated demand of 578,698 tons a month in 1944 was 140 percent of the expected demand (412,072 tons).

Relation of indicated average monthly asphalt demand in the United States to basic trend, 1925-44, by years

Year	Long-time trend, 1908-44 (short tons)	Indicated average monthly demand (short tons)	Relation of indicated average monthly demand to trend (percent)

FOREIGN TRADE

Imports.—Imports of natural asphalt and bitumen into the United States in 1944 totaled 8,235 short tons valued at \$254,135 compared with 8,142 tons valued at \$221,503 in 1943. Imports of lake asphalt from Trinidad increased from 6,966 short tons valued at \$202,082 in 1943 to 8,062 tons valued at \$249,866 in 1944, but imports of grahamite from Cuba decreased from 999 tons valued at \$17,900 to 102 tons valued at \$2,242.

Imports of solid asphalt increased from 101,089 short tons valued at \$567,832 in 1943 to 116,119 tons valued at \$652,221 in 1944. Of the 1943 and 1944 imports, virtually all came from the Netherlands West Indies.

	84,804	1,585,493	91,139	2,280,620	116,554	2,551,723

In addition, 51,409 barrels (9,347 tons) valued at \$91,001 of liquid petroleum asphalt, including cut-backs and road oil, were imported in 1943 and 13,033 barrels (2,370 tons) valued at \$20,801 in 1944. Mexico supplied all the liquid petroleum asphalt imported in 1943, and the Netherlands West Indies all imported in 1944.

Exports.—Exports of petroleum asphalt increased 27 percent from 1943 to 1944 but still were little more than half of the corresponding exports of 1941. The principal gains were in exports to the south-western Pacific, where large shipments to Australia were only partly offset by decreased exports to New Zealand. In Asia, shipments of petroleum asphalt to British India more than trebled from 1943 to 1944. Brazil accounted chiefly for the greater shipments of asphalt to South America in 1944 than in 1943. Portugal received three-fourths of the small exports to Europe in 1944. In North America small increases in exports of asphalt to Canada, Cuba, and the Republic of Panama were insufficient to offset the general decline in asphalt shipments to neighboring countries.

ROAD OIL

The manufacture and sale of road oil were reported in 1944 chiefly by Texas, California, and the Rocky Mountain district. What was sold in 1943 and 1944 as road oil might better have been described as liquid asphalt, as the use of road oil for highway purposes was officially prohibited for most of the year.

For 10 months of 1944, Petroleum Directive 72 of the Petroleum Administration for War, dated September 9, 1943, continued its restrictions on the delivery or acceptance of road oil for use as a paving material or as a dust palliative. By an amendment of November 1, 1944, Petroleum Directive 72 was revoked except for Washington, Oregon, California, Nevada, and Arizona. Accordingly, the statistics of road oil for 1944 refer to liquid asphalts having a penetration less than 350 after distillation to 680° F.

POSTWAR PROSPECTS

Although funds, materials, and labor were expended in 1944 to repair and maintain the Nation's highways and compensate for wartime wear and tear, it is evident that at the end of the war extensive reconstruction of the network of roads will be needed. The Federal Highway Act of 1944, passed late in the year, provides one-half billion dollars a year for each of 3 years following the war, to be matched equally by the States, counties, or cities receiving the funds. The act requires that the States, acting jointly, shall designate a national system of interstate highways, not exceeding a total of 40,000 miles, to be integrated with the Federal-aid system. Where necessary, the National Interregional Highway Committee recommended that existing highways be rebuilt to modern superhighway standards or be replaced by new highways where modernization would be impracticable or undesirable.¹ All this should create a good market for paving asphalt, paving flux, cut-back asphalts, and asphalt emulsions.

The Engineering News-Record estimated that 900,000 to 1,600,000 dwelling units will be needed annually for the first 10 postwar years, as a result of the general lack of residential construction during the war years. Many manufacturers undoubtedly will build new industrial plants rather than endeavor to adapt idle munition plants to their specialized needs. All this should serve to prolong the wartime demand for roofing asphalt and flux, waterproofing asphalt, mastic, pipe coatings, and paints and enamels.

¹Engineering News-Record, vol. 134, No. 6, Feb. 8, 1945, pp. 109-110.

SUMMARY

The decline in production and demand for cements, which began in 1943, continued throughout 1944. Total production of 92,152,399 barrels of hydraulic cements was 32 percent below the 1943 figure. This reduction results from respective decreases of 32 percent in the output of portland cement and of a grouping of all other hydraulic cements (natural, masonry, puzzolan, and hydraulic lime). The portland-cement industry operated at 38 percent and the "All other" group at 36 percent of productive capacity in 1944. Mill shipments were 26 percent below 1943 volume and totaled 95,592,155 barrels. Demand for portland cement and the group of all other hydraulic cements, as gaged by shipments, declined nearly one-fourth from 1943. Stocks of all hydraulic cements at mills on December 31, 1944, were 19,976,371 barrels or 15 percent below the quantity on hand at the close of 1943.

The average net mill realization per barrel of portland cement increased 2 cents over 1943 to \$1.59 in 1944, whereas that for "All other hydraulic cements" dropped 4 cents to \$1.24 in 1944.

The decline in the long-term down trend of finished cement, which began in February 1943, continued at an accelerated rate through the first 4 months of 1944. Easement in the rate of decline began in May and continued through the remainder of the year.

Monthly production of cement from January through August 1944 bore little resemblance to the usual peacetime seasonal pattern. Although the trend for January and February was similar to that of a normal period actual production was much greater. This increase is attributed to a larger than usual proportion of construction in the Southern and Far Western States, where structural activity was not seriously curtailed by winter weather. From March to May the month-to-month increases in output were well below the customary seasonal rates of gain. However, in each month from May to August production increased over each preceding month in greater proportions than the usual seasonal pattern. From August to December the production trend followed the typical seasonal pattern. Peak 1944 production was reached in October.

¹ Compiled from monthly reports by producers.² Value received f. o. b. mill, excluding cost of containers.³ Revised figure.

Monthly shipments in 1944 advanced from the January-February level of slightly more than 5 million barrels to 10,758,000 barrels in August, the largest monthly volume of the year. The volume fell slightly through September and October and rapidly through November and December, reaching the lowest monthly quantity of the year in the latter month.

In 1944 the Middle States displaced the Southern States as the leading cement-consuming region in continental United States (see fig. 1). Consumption in all regions¹ in 1944 as indicated by destination of shipments declined from 1943 levels.

The declines in output and mill shipments of cement in 1944 were less severe than the falling-off in total construction activity, which was estimated on a value basis by the United States Department of Commerce to be 50 percent below 1943. Contracts for engineering construction, as reported by the Engineering News-Record, were approximately one-third below 1943. Portland Cement Association data show that contracts were awarded in 1944 for 32,741,413 square yards of paving—a decline of 54 percent from the 1943 total of 71,089,671 square yards. As reported by the War Production Board, construction work financed by public funds represented 61 percent of the total construction in 1944 compared with 80 percent in 1942 and 1943. The sharpest decrease in construction was in military establishments such as troop housing, airfields, and storage facilities.

War controls on the cement industries were eased during 1944 and were directed primarily toward increasing the maximum price per

¹ Bureau of Mines, Minerals Yearbook, 1942, p. 1204.

FIGURE 1.—Trends of indicated consumption of portland cement in continental United States, 1928-44, by regions.

barrel to compensate for increased production costs and declining sales volume.

General Limitation Order L-179 on the portland-cement industry, which restricted production of cement to three types—"normal," "high-early-strength," and "moderate-heat"—effective August 23, 1942, was revoked November 25, 1944.

Maximum Price Regulation Order 224 of the Office of Price Administration was amended three times during 1944 to allow price increases in several areas. - Effective April 20, an increase of 20 cents per barrel was granted for the Northeastern States; 10 cents per barrel on August 30 for Michigan, Ohio, West Virginia, western Pennsylvania, part of eastern Kentucky, and western Virginia; and 20 cents per barrel on October 14 for southern California, Arizona, and southeastern Nevada.

The problem of labor shortages and labor turn-over greatly increased costs of production in 1944. Fixed production costs per barrel of output, such as capital investment, plant depreciation, cost of supplies, fuel, and repair parts, also continued to increase as the volume of production fell with the declining demand for cement.

PORTLAND CEMENT

PRODUCTION, SHIPMENTS, AND STOCKS

The annual production of portland cement represents 99 percent of the total output of all hydraulic cements. Thus the general conditions affecting the activity of the portland-cement industry during 1944 were largely those given in the preceding summary.

Finished portland cement produced, shipped, and in stock in the United States, 1943-44

In 1944 portland cement was manufactured at 143 plants and shipments were made from 151 plants in 34 States and Puerto Rico. Ten plants shipped from stocks. The leading States, in order of production, were California, Pennsylvania, Texas, Michigan, and Alabama.

Production in 1944 was lower in all Bureau of Mines districts in continental United States than in 1943; the rates of decline ranged from 13 percent in Oregon and Washington to 53 percent in Kansas. The output in Puerto Rico in 1944 increased 44,484 barrels over the previous year.

Shipments from mills during 1944 were below production in seven districts—Michigan, Alabama, Tennessee, Eastern Missouri-Minnesota-South Dakota, Colorado-Wyoming-Montana-Utah-Idaho, Oregon-Washington, and Puerto Rico. These districts, only, show an increase in stocks on December 31, 1944, over the corresponding date of 1943.

Stocks of finished cement were in a favorable condition at the beginning of 1944 and reached a peak in February after which they followed the same seasonal trend as that of the preceding year.

FIGURE 2.—Trends in end-of-month stocks of finished portland cement and portland-cement clinker, 1939-44.

Clinker stocks were also in good supply at the beginning of 1944 and reached their peak in April. They declined from May through November but finished the year with an upward swing in December.

Stocks of finished portland cement and portland-cement clinker at mills in the United States on December 31 and yearly range in end-of-month stocks, 1940-44

¹ Revised figure.

DOMESTIC CONSUMPTION

Indicated consumption of portland cement in 1944 was above 1943 only in Minnesota, Montana, North Dakota, and Wisconsin and was lower in all other States and the District of Columbia. The changes in regional consumption are illustrated in figure 1.

¹ Shipments by producers to foreign countries and to noncontiguous Territories of the United States (Alaska, Hawaii, Puerto Rico, etc.), including distribution from Puerto Rican mills.

LOCAL SUPPLIES

As parts of some States or areas are commonly supplied from mills of neighboring States within normal shipping range, the data listed in the following table do not indicate areas or States in which a definite shortage of cement existed. The total surplus of producing States in 1944 was distributed as follows: 11,479,948 barrels to non-cement-producing States, 6,131,741 barrels to destinations outside continental United States (excluding local consumption of Puerto Rican production), and 184,727 barrels to unspecified destinations.

Estimated surplus or deficiency in local supply of portland cement in cement-producing States, 1943-44, in barrels

TRANSPORTATION

The methods of shipping portland cement from producing mills in 1944 show only minor changes from the previous year. The percentage of total shipments moved by boat and truck increased slightly, and the movement by railroads decreased. This trend in methods has been constant since 1942, the first full war year.

There was a sharp drop in the proportion of cement shipped in bulk in 1944 and a corresponding increase in the proportion moved in containers. Despite the paper shortage the percentage moved in paper bags increased from 36.1 in 1943 to 46.2 in 1944, and although the total quantity of cement moved in bulk decreased the percentage of bulk shipments moved by boat increased 1.6 percent.

Shipments of portland cement from mills in the United States, 1942-44, in bulk and in containers, by types of carriers

¹ Includes steel drums and iron and wood barrels.

² Includes shipments for Puerto Rico.

³ Includes cement used at mills by producers as follows—1942: 181,642 barrels; 1943: 153,337 barrels; 1944: 112,593 barrels.

⁴ Less than 0.05 percent.

MILL VALUES

The average net mill realization of all portland cement shipped from mills in 1944 advanced to \$1.59 per barrel from \$1.57 in 1943. The gain in average mill return resulted largely from the increased proportion of special cements shipped and the price increases allowed in several sections of the country by the Office of Price Administration.

The composite wholesale price of portland cement, f. o. b. destination, according to the Bureau of Labor Statistics index (1926=100), was 95.8 in 1944, an increase of 2 points over the 1943 figure of 93.8.

CAPACITY OF PLANTS

The aggregate annual capacity of all portland-cement plants in 1944 declined about 2 million barrels from 1943. This decrease was due largely to shortages of manpower, fuel, and the closing and dismantling of one of the mills. Data for 1944 are based on figures of 154 mills throughout the year. The over-all rate of operation in 1944 was at 37.8 percent of total capacity. Plant activity in 1944 was appreciably higher in Virginia, Georgia, Florida, Louisiana, the Pacific Coast States, and Tennessee than in the remainder of the country.

The number of plants with capacity under 1,000,000 barrels on December 31, 1944, was 42 compared with 44 on the same date of 1943. An increase is reported in 1944 for the plants with capacities between 1 million to 2 million and 3 million to 10 million barrels.

The percentage of capacity used in each month of 1944 was lower than in the corresponding month of 1943. The monthly rate of operation was lowest in February and March of 1944. It began an upswing in April which continued to a peak in October and declined through November and December.

The total capacity of wet-process mills exceeded that of dry plants in 1944 as in the previous year. The closer control of raw materials obtained in the wet-process plants accounts for the greater utilization of the process.

CLINKER PRODUCTION

Production of clinker, the intermediate product of the industry, was 33.3 percent below 1943. However, stocks at the mills on December 31, 1944, although below that of the corresponding date of 1943, were at a satisfactory operating level.

¹ Compiled from monthly estimates of the producers.

PRODUCTION ACCORDING TO RAW MATERIALS

Portland-cement plants using limestone and clay or shale in 1944 supplied 72.0 percent of the total production compared with 69.2 percent in 1943. The proportion of the production made from cement rock and pure limestone and from blast-furnace slag and limestone declined slightly from 1943, and marl and clay increased 0.6 percent. The continued predominance in 1944 of the mixture of limestone and clay or shale as the leading raw material is attributed to the greater activity of the southern and western mills which use this mixture almost entirely as raw material.

Production and percentage of total output of portland cement in the United States, 1898-1914, 1926, 1929, 1933, 1935, and 1941-44, according to raw materials

¹ Includes oystershells.² Includes bentonite, diatomaceous shale, and fuller's earth.³ Includes silica and quartz.⁴ Includes iron ore, pyrite cinders and ore, and mill scale.⁵ Includes diatomite, fluorspar, pumelite, flue dust, pitch, red mud and rock, hydrated lime, tufa, cinders, calcium chloride, sludge, grinding aids, and air-entraining compound.**FUELS AND POWER**

The consumption of all types of fuel in 1944 was below that of 1943. This is in line with the lower rate of activity in the cement industry. Stocks of all types of fuel were low and rarely were sufficient at the average monthly consumption rate to maintain operations for more than 2 months without receiving additional supplies.

TYPES OF CEMENT

A break-down of total production of portland cement in 1944 by various types is presented in the following table. Although the overall production and shipments of cement in 1944 was lower than the previous year, production and demand for oil-well, portland-puzzolan, and miscellaneous types of cement was greater in 1944.

Prepared masonry mortars.—Production of these mixed materials in 1944 from 68 plants totaled 2,267,333 barrels and shipments 2,210,262 barrels, valued at \$3,493,971 an average mill realization of \$1.58 per barrel. These data are not included in the statistics of this chapter, but the portland cement used in producing the mixtures is included.

Portland cement produced and shipped in the United States, 1940-44, by types

Kind and year	Active plants	Production (barrels)	Shipments		
			Barrels	Value	
				Total	Average
General use and moderate heat (types I and II):

¹ Figures reported separately for the first time in 1943.

² Includes air-entrained and Vinsol resin cements classed as modified cements by producers.

³ Bureau of Mines not at liberty to publish figures separately.

⁴ Revised figure.

⁵ 1940-42: Includes hydroplastic and plastic portland cements; 1943-44: Includes hydroplastic, plastic, and waterproofed cements.

NEW DEVELOPMENTS

Several cement mills have changed to the manufacture of chemical lime through their rotary kilns. However, the Manitowoc Portland Cement Co., Manitowoc, Wis., a subsidiary company of the Medusa Portland Cement Co., Cleveland, Ohio, is manufacturing simultaneously chemical lime for war industries and standard portland cement.²

New trends in the cement industry in 1944 were directed primarily toward war-born products developed because of shortages of other materials. Some of these are concrete beams to replace steel in the construction of industrial buildings, concrete tanks substituted for steel tanks in many applications, increased manufacture of concrete burial vaults with little or no reinforcing steel, and concrete joist floors which have replaced wood construction. A high-strength lightweight concrete has been developed in the Northwestern University Technological Institute.³ The exceptional strength is obtained by compressing the concrete and reducing the amount of water in the mix.

Interest in air-entraining cement also continues to grow, and more confidence seems to be placed in this relatively new type concrete. Investigations concerning the type and method of adding the air-entraining agents by the Central Concrete Laboratory of the United States Engineers, Mount Vernon, N. Y., have shown that the variability of the air content can be reduced by using neutralized Vinsol resin (sodium resinate) rather than unneutralized flake Vinsol resin.⁴ Experiments concerning the mesh size of sands that provide the required amount of air entrapment have also been made.⁵

The Permanente Cement Corp. (California) has set a new record for the industry by making 20,328 barrels of cement in a 24-hour period. The former record was 18,830 barrels.

NATURAL, MASONRY (NATURAL), AND PUZZOLAN CEMENTS

Production and shipments of the group of hydraulic cements other than portland in 1944 decreased 32 and 29 percent, respectively, from the previous year's total. Stocks also decreased and were 32 percent below the 1943 total. Producers reported the consumption of 17,845 short tons of coal and of gas equivalent to approximately 107 short tons of coal.

Natural, masonry (natural), and puzzolan (slag-lime) cements produced, shipped, and in stock at mills in the United States, 1940-44

Year	Production		Shipments		Stock (Dec. 31)
	Active plants	Barrels (376 pounds)	Barrels (376 pounds)	Value	Barrels (376 pounds)
1940.....	12	2,534,566	2,514,597	\$3,386,801	259,868
1941.....	12	2,875,962	2,926,203	3,967,567	199,365

POSTWAR OUTLOOK

Although there was little increase in cement-plant capacity during the war, available facilities enabled the industry to attain an all-time high production of more than 185 million barrels during the intensive war-construction period of 1942. Thereafter production declined greatly, but despite manpower shortages and shrinking markets the plants as a whole have been kept in operating condition. The industry is therefore ready to take advantage of the anticipated enormous postwar building program which the F. W. Dodge Corp. has estimated will exceed 15 billion dollars in the region east of the Rocky Mountains. Furthermore the planned 3-year program of postwar highway construction exceeds 3 billion dollars. The magnitude of the cement market implied by these figures may be estimated in the light of studies made by the Public Works Administration on the proportion of the construction dollar that is spent for cement. These studies show that for the construction of buildings the percentage is 4, for sewage-disposal systems 9, for streets and roads 10, and for reclamation projects 11.

In view of the postwar construction plans of the Government and industry, termination of the war will effect almost immediately an expansion in the production of cement.

The ruling of the Federal Trade Commission abrogating the basic point price system may lead to greater decentralization of cement plants or to the production of clinker only at the present large mills, with shipment of clinker to grinding mills nearer the established markets.

Closer control of raw materials and more exact specifications will be expected for the postwar industry, but because of the expected sellers' market for the years immediately following the war, purchasers probably will accept the current five standard types of cement.

Although increased production ordinarily tends to lower prices no reduction is expected in the immediate postwar period because of the increased costs of fuel and power and the probable increase in labor costs.

FOREIGN TRADE *

With the cessation of hostilities in Europe import and export figures from all countries may be released.

Imports.—Imports of all hydraulic cements except white nonstaining portland cement, 1942-44, are listed by country of origin in the second table following. Imports of white nonstaining cement totaled 304 barrels valued at \$1,201 in 1942, but in 1943 and 1944 no imports of this type of material were received.

Hydraulic cement imported for consumption in the United States, 1940-44

Year	Barrels	Value	Year	Barrels	Value
1940.....	538,060	\$506,191	1943.....	13,658	\$55,500

	340	819	13,658	55,548	169	418

¹ Excludes "white, nonstaining, and other special cement."

² Less than 1 barrel.

Exports.—Exports of cement to foreign countries in 1944 were greater than in any other recent year. The increase is attributed largely to expanded requirements of the Latin American countries, the principal United States export market, and to a sharp rise in demands from Iran, Arabia Peninsular States, and the State of Bahrein. Exports of hydraulic cement from 1940 through 1944 and exports by countries of destination for 1942 through 1944 are given in the following tables.

Hydraulic cement exported from the United States, 1940-44

WORLD PRODUCTION

Production of cement in 1944 continued to decline in the United States and Canada as in the previous year. However, production increased in Mexico and in the Central and South American countries.

World production of hydraulic cements, 1939-44, by countries, in metric tons¹

REVIEW BY COUNTRIES

Brazil.—On January 15, 1944, the import duty on portland cement and roman cement received in Brazil was suspended for 90 days. Domestic production of cement comes largely from the States of São Paulo and Rio de Janeiro. The first plant producing white portland cement in Brazil began operations in August 1943. Inadequate fuel supplies and transportation problems are still a limiting factor in the production of cement in Brazil.

Chile.—The cement requirements of Chile continue to increase. As the war shut off the supply of new equipment, the property of Thomas A. Edison, Inc., at Piscataway, N. J., was purchased and shipped to Chile to be used in the construction of a cement plant. Construction was begun early in March 1944 on the new plant at Juan Soldada, near La Serena, Chile. The supply of raw material at this locality is believed to be sufficient for 70 years at an annual consumption rate of 200,000 metric tons.

Colombia.—By 1941 the production of cement by domestic plants was sufficient for the country's needs. Cement was not imported in 1941-42, and an export market was opened in 1943. In 1944 the output of cement again increased as new plants were built in the interior of the country.

India.—It is reported that the cement-production capacity of India is about 2,500,000 tons a year, which more than doubles the prewar output. There are 23 factories producing cement, but only about 10 percent of current production is available for civilian consumption as the bulk of the output is required for public works and defense requirements.

Mexico.—The United States Mexican Commission for Economic Cooperation which was created in May 1943, announced during 1944 a Nation-wide development program for the portland cement industry in Mexico. Five existing plants have been enlarged, and new plants are under construction at Cuernavaca, Lagunas, Merida, Monterrey, Nuevo, and Orzaba.

Spain.—The output of cement in Spain began an upswing in 1941 which continued through 1943 the latest year for which figures are available. However, it is believed that production continued to expand through 1944.

Sweden.—Production of cement in Sweden decreased from 1939 through 1941. However, production and consumption began an upswing in 1942 that continued through 1944. Further expansion of domestic production is limited by the lack of coal.

Turkey.—It has been reported that the Government of Turkey took over all the cement plants in 1944. An upswing in output began in 1942 and continued through 1944. Two new plants, one at Ankara and the other at Sivas, were completed in 1943.

U. S. S. R.—New cement plants were constructed in Dneprodzerzhinsk in th Ukraine, and at Novosibirsk in 1944. Another plant at Krasnoyarsk, Krai, and two technical schools at Novosibirsk to restore and operate cement plants are expected to be in operation early in 1945.

Venezuela.—The importation of portland cement into Venezuela was again encouraged in 1944 to relieve the continued shortage.

The lifting of import duties on cement, which became effective on December 7, 1942, was continued to May 7, 1944, and a reduction in

wharfage charges has been made to establish a uniform charge on cement entering the various Venezuelan ports. Plans for several plants are being considered. The new plants when completed will not only make the country self-sufficient but will also furnish a considerable quantity for export.

Yugoslavia.—The cement production in Yugoslavia comes from 5 plants in Dalmatia. The chief raw material is Dalmatian cement marl. A recent report states that a process has been discovered that transforms low-grade bauxite into a quick-setting cement known locally as "electro cement." Annual production is reported to be 750,000 metric tons per year.

GENERAL CONDITIONS

Sales of crushed and dimension stone combined (155,579,580 tons) were 9 percent less in 1944 than in 1943 and 21 percent less than the all-time high record of 1942. The total value of sales (\$175,642,157) was 5 percent less than in 1943. Sales of crushed and broken stone continued to decline, as Government construction was small, highway programs were suspended pending termination of the war, and private construction was almost negligible. Dimension stone sales dropped to the lowest point in the recorded history of the industry. Such a condition was not unexpected because the types of construction required for military needs demand minimum quantities of building stone, and both private and Government construction of large permanent buildings in which stone is normally used was almost at a standstill. The total value of sales, however, increased. Crushed and broken stone output declined 9 percent in quantity and 6 percent in value. Dimension stone (including slate) declined 25 percent in quantity but increased 8 percent in value.

This chapter follows the general plan introduced in 1938 whereby crushed stone and dimension stone are considered separately, except in the introductory general tables.

The tables of this report give the quantities sold or used by producers and the values f. o. b. quarries and mills. Stone quarried and used by producers is considered as sold and is included in the statistics of sales. The data, however, do not include stone made into abrasives (such as grindstones) or that used in making lime and cement. These materials are reported in terms of finished products in the Abrasive Materials, Lime, and Cement chapters of this volume. The following tables show the total sales of stone by kinds, uses, and States.

Stone sold or used by producers in the United States, 1940-44, by kinds

DIMENSION STONE

Dimension stone and crushed stone are so diverse in character and use that they are considered in separate sections of this chapter. The term "dimension stone" is applied to blocks or slabs of natural stone, most of which are cut to definite shapes and sizes. The principal uses of dimension stone are for construction of masonry walls and for memorials. Crushed and broken stone, on the other hand, consists of irregular fragments or grains, sized chiefly by mechanical screening or air separation. The principal uses are as roadstone, concrete aggregate, railroad ballast, furnace flux, and a great variety of industrial applications that have little or no relation to masonry construction.

Dimension-stone producers may be divided into three main groups upon the basis of plant operation. The first group quarries stone and sells it as rough blocks or slabs; the second quarries stone and also manufactures it into finished products; and the third buys sawed slabs or rough blocks of stone and manufactures them into finished products but does not operate quarries. The Bureau of Mines statistical canvass covers the first and second but not the third group. Bureau of Mines statistics are compiled from reports of quantities and values of original sales; hence they include some material sold as rough blocks and some sold as finished products.

Total sales of dimension stone in 1944 declined 25 percent in quantity but increased 8 percent in value compared with 1943. These over-all figures include slate, but details of this branch of the industry are given in the separate chapter on Slate.

The following table presents salient statistics for 1943 and 1944:

Dimension stone sold or used by producers in the United States, 1943-44, by kinds and uses

¹ Includes soapstone, mica schist, volcanic rocks, argillite, and other varieties that cannot be classified in the principal groups.

² Details of production, by uses, are given in the chapter on Slate in this volume.

BUILDING STONE

The use of stone as a material of construction antedates the most ancient historic records. It has always occupied an important place in the construction of monumental buildings, but it has found very limited use under wartime conditions. Sales in 1944 dropped even lower than the all-time low of 1943. The following table gives the quantity and value of each kind of building stone sold in 1944.

Building stone sold or used by producers in the United States in 1944, by kinds

Kind	Rough			
	Construction		Architectural	
	Cubic feet	Value	Cubic feet	Value

¹ For granite, sawed stone corresponds to dressed stone for construction work (walls, foundations, bridges) and cut stone to architectural stone for high-class buildings.

GRANITE

Sales of granite in the form of blocks or slabs remained virtually unchanged in quantity but gained 14 percent in value in 1944 compared with 1943. The relatively high value was due primarily to larger sales of cut and dressed stone, and smaller sales of the lower-priced rough construction stone and rubble. Sales of rough construction stone were less than half as large and rubble two-thirds as large as in 1943. Architectural stone declined slightly, but memorial stone production made substantial gains. Sales of rough monumental stone increased 16 percent in both quantity and value and dressed monumental stone registered an advance of 15 percent in quantity and 14 percent in value. The number of paving blocks sold gained slightly. A large proportion of the 1944 output consisted of the small dux blocks. Curbing production was nearly two and one-half times as great as in 1943.

The average selling price of dressed building stone was 30 cents a cubic foot higher in 1944 than in 1943, whereas prices of rough and dressed memorial stone declined 1 and 5 cents, respectively, per cubic foot.

Granite (dimension stone) sold or used by producers in the United States in 1944, by States and uses

¹ Through the kindness of the Granite Manufacturers' Association, Barre, figures covering the entire granite industry of the Barre district are given in this table to supplement figures of sales reported by quarrymen.

BASALT AND RELATED ROCKS (TRAP ROCK)

Basalt and related rocks are not used extensively as building stone. The industry experienced the most serious decline in its history in 1944. Total sales were only 15 percent in quantity and 14 percent in value of those recorded in 1943. Basalt and related rocks are used to some extent for memorials, but such stones are classed in trade as black granite and are therefore included with the figures for monumental granite.

Basalt and related rocks (trap rock) (dimension stone) sold or used by producers in the United States in 1944, by States and uses

MARBLE

Although marble sales gained in every category in 1944 compared with 1943, they were still below those of 1935 at the lowest level of the depression period. The value of sales in 1944 was, however, higher than in either 1934 or 1935. The increase in 1944 over 1943 amounted to 20 percent in quantity and 26 percent in value. Building marble registered the largest gains—29 percent in quantity and 30 percent in value. Sales of monumental stone increased 16 percent in quantity and 24 percent in value. The average value per cubic foot of building marble increased less than 1 percent and of monumental marble 7 percent. Although the quantity of building marble sold was only a fraction of that used in the predepression era, the substantial gain is a hopeful sign. When the erection of large public buildings is again a widespread activity, marble may regain its rightful place as an important material of construction.

LIMESTONE

Limestone blocks cut to definite shapes and sizes are used almost exclusively for building purposes. Under normal conditions limestone is used extensively, particularly for interiors and exteriors of public buildings of all kinds, such as post offices, museums, churches, schools, and court houses, as well as commercial buildings. The erection of such buildings virtually ceased when the industry and manpower of the Nation became focused on the all-important problem of winning the war. Accordingly, the building limestone industry was greatly restricted in 1944. The Indiana Limestone Co., normally the largest producing unit in the industry, produced no stone in 1944; it devoted its equipment and personnel to manufacturing activities directly connected with the war. Other limestone companies likewise devoted their skill and facilities, at least in part, to war work.

Total sales in 1944 were 32 percent less in quantity and 22 percent less in value than in 1943. The principal decline in 1944 was in the crudest form of building stone, classed as rubble; sales fell to less than one-half of those recorded in 1943. Rough construction stone sales were a little lower than in 1943, but both rough architectural and finished (cut and sawed) stone increased slightly. Although the gains are small, they at least convey the inference that the worst is over and that an upward movement is at last under way in the use of high-grade building stone. An upward trend certainly would be welcomed because the value of sales of building stone (excluding rubble) in 1944 (\$539,707) was less than 3 percent of the value in 1929 (\$20,649,257).

The most productive area in the United States is centered in the vicinity of Bedford and Bloomington, Ind. This area supplied 81 percent of the rough architectural and finished (sawed and cut) limestone sold in 1944.

SANDSTONE

Sandstone in the form of dimension stone is used chiefly as building stone. The harder varieties are used for paving stones, but this branch of the industry has declined to an almost insignificant figure during the past 15 years. The manufacture of curbing and flagging has also declined but less drastically than paving-stone manufacture. Sandstone is used for making grindstones, pulpstones, and whetstones, but statistics on these commodities are included in the chapter on Abrasive Materials.

Sales of dimension sandstone declined 27 percent in quantity but only 1 percent in value in 1944 compared with 1943. Declines were registered in every category except sawed building stone, which gained 12 percent in quantity. Unit values were considerably higher for rough construction stone, cut building stone, rubble, curbing, and flagging. Prices were lower for rough architectural stone and sawed building stone.

Ohio is the principal producer. Its quarries furnished 60 percent of the total value of output in 1944. Other producing States, in order of sales value, were New York, Pennsylvania, Tennessee, and West Virginia.

The second table following presents a 22-year history of the bluestone industry. Bluestone is a type of sandstone that splits readily into thin, uniform sheets. It is particularly well-adapted for flagging but is used also for building stone and curbing. Although sales in 1944 were 56 percent greater than in 1943, they were only 25 percent of those in 1923.

¹ Included under "Undistributed."² Building stone (rough and dressed), approximately 273,070 cubic feet; flagging, approximately 11,840 cubic feet.**TRENDS IN USE OF DIMENSION STONE**

The history of production of dimension stone by kinds, for a 29-year period is indicated in figure 1. A healthy peacetime prosperity is most conducive to activity in the building stone industry. Building stone finds little use in war, a fact well illustrated by the low sales figures for 1918 and 1944 shown in figure 1. The trough of 1931 to 1936 indicates furthermore that industrial depressions react strongly to the detriment of the industry. The promising movement toward recovery in 1939 was cut short by the war in Europe, the unhappy postlude of which precipitated these industries to the lowest depths of adversity in their history.

FIGURE 1.—Sales of dimension stone in the United States, by kinds, 1916-44.

FIGURE 2.—Sales of all building stone and building limestone compared with nonresidential construction (public and private), 1915-44. Data on nonresidential building construction from Bureau of Foreign and Domestic Commerce.

Figure 2 traces for a 30-year period the history of production of all building stones and of the principal variety—limestone—in their relation to nonresidential building, the class of construction using stone most extensively. Activity in building stone production in peacetime follows generally the trend of nonresidential construction, but wartime construction that reached a peak in 1942 failed to stimulate the building stone industry, which has declined steadily since 1939. In 1944 nonresidential construction continued its precipitous decline of 1943. Building stone continued to decline and reached the lowest point in its recorded history.

FUTURE OUTLOOK

The dimension-stone industries have experienced the most serious set-back in their history during the war years. Now that hostilities in Europe have ceased, the prospect for recovery appears on the horizon. That prospect can be measured to some extent by estimates of postwar construction. According to the F. W. Dodge Corp., postwar building projects contemplated for the area east of the Rocky Mountains have a total value of nearly 15 billion dollars. Projects valued at more than 7 billion dollars have progressed to the design stage. As this total is measurably greater than the value of contracted work in any previous peacetime year, the stone industries may view the future with some measure of confidence. The quantity of stone to be used in postwar building will depend upon how large a part of the planned construction will consist of public and commercial building of types that normally employ stone as a major building material. It will depend too upon the extent to which brick, terra cotta, and architectural concrete or other alternative products may be used, and trends in the use of such products cannot be forecast at this time. Very few churches, college buildings, museums, post offices, or other large structures in which stone is used have been built during recent years, and the accumulated need bears promise of growing markets with the advent of a peacetime environment under which the building stone industries thrive.

Memorial stone production, which is an important branch of the granite and marble industries, has been maintained at relatively high levels. The sale of memorials is governed largely by buying power and population and therefore is influenced indirectly only by industrial or building activity. Stone producers have the prospect of enlarged sales for several years to supply material for numerous war memorials.

CRUSHED AND BROKEN STONE

Nearly 155 million short tons of crushed and broken stone were sold in 1944, exclusive of that used for making cement and lime. Sales decreased 9 percent in quantity and 6 percent in value compared with 1943. The average value at the quarry increased 4 cents a ton.

The accompanying table of salient statistics shows the quantity sold and the value of sales during 1943 and 1944, by uses. Detailed data on asphaltic stone and slate granules and flour are given in the chapters on Asphalt and Slate.

Crushed and broken stone sold or used by producers in the United States, 1943-44, by principal uses

Use	1943			1944		
	Short tons	Value		Short tons	Value

² To avoid disclosing confidential information certain totals are somewhat incomplete, the figures not included being combined under "Undistributed."

COMMERCIAL AND NONCOMMERCIAL OPERATIONS

The accompanying table shows the production of crushed stone for concrete and road metal during recent years by Government agencies of various kinds, contrasted with that by commercial enterprises. For several years prior to 1940 Government-sponsored enterprises produced 29 to 46 percent of the total output. They consisted principally of make-work organizations designed to meet unemployment and, to a lesser extent, State, county, and city highway boards or commissions. War conditions brought about a radical change in the situation. Unemployment ceased to be a problem. Highway construction, except for military roads, was virtually suspended; consequently the output of stone by State and county organizations was very small. It is not

surprising therefore that noncommercial production dropped to only 9 percent of the total in 1943. However, the percentage increased to 12 in 1944.

Concrete and road metal sold or used by commercial and noncommercial operators in the United States, 1940-44

[Figures for "noncommercial operations" represent tonnages reported by States, counties, municipalities, and other Government agencies, produced either by themselves or by contractors expressly for their consumption, often with publicly owned equipment; they do not include purchases from commercial producers. Figures for "commercial operations" represent tonnages reported by all other producers]

Year	Commercial operations				Noncommercial operations				Total

GRANULES

Statistics on roofing granules of all kinds were compiled for the first time in 1943. Data are now available for 3 years, as follows.

Roofing granules sold or used in the United States, 1942-44, by kinds

Year	Natural		Artificially colored		Brick		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1942.....	352,320	\$2,650,503	538,310	\$7,594,174	43,230	\$636,961	933,860	\$10,881,638
1943.....	287,090	2,190,143	543,870	7,745,452	47,650	716,685	878,610	10,652,280
1944.....	287,080	2,210,379	637,090	9,313,356	65,830	1,005,964	990,000	12,529,699

METHODS OF TRANSPORTATION

The following table shows the quantities of commercial crushed stone for concrete and road metal conveyed during 1943 and 1944 by each of the principal methods of transportation. During 1942 and 1943 there was a trend from truck to rail haulage; but in 1944 it was reversed, truck haulage assuming about the same proportions as in 1941.

*Stone for concrete and road metal sold or used by commercial producers in the United States, 1943-44, by methods of transportation*¹

Method of transportation	1943		1944	
	Short tons	Percent of total	Short tons	Percent of total
Truck.....	41,457,070	55	36,835,560	65
Rail.....	22,248,420	30	15,593,350	27
Waterway.....	3,241,420	4	1,813,980	3
Unspecified.....	7,959,700	11	2,573,060	5
	74,906,610	100	56,815,950	100

¹ For practical purposes the entire output of noncommercial operations commonly is moved by truck. Including noncommercial production, crushed stone for concrete and road metal moved as follows—1943: Truck 59 percent, rail 27 percent, water 4 percent, and unspecified 10 percent; 1944: Truck 69 percent, rail 24 percent, water 3 percent, and unspecified 4 percent.

GRANITE

Sales of crushed and broken granite declined 21 percent in both quantity and value in 1944 compared with 1943. Riprap sales were nearly three times as great as in 1943 because of an unusual demand in California for stone to be used in breakwater and jetty construction. The average selling price per ton was 25 cents higher than in 1943. Sales for concrete aggregate and road stone, the largest use, were only about two-thirds as great as in 1943, and the value of sales was even lower as the price per ton declined 10 cents. A low level of sales was to be expected because of inactivity in highway and building construction. Railroad ballast sales gained 4 percent in both quantity and value. The extremely heavy burden of transportation placed upon the rail lines in 1944 made it imperative that road beds be kept in condition. The average sales value of ballast remained unchanged. A moderate gain in sales for other uses was due primarily to increased demands for poultry grit.

The number of individual operations supplying noncommercial crushed stone cannot be determined with any degree of accuracy from the reports submitted. Therefore, in the accompanying tables covering granite and other kinds of crushed and broken stone, the number of active plants is not given. For many years before 1939, when noncommercial production was less important, such figures appeared in the tables.

BASALT AND RELATED ROCKS (TRAP ROCK)

Sales of crushed and broken trap rock were 2 percent less and the value was 3 percent less in 1944 than in 1943. This classification includes the dark igneous rocks—basalt, gabbro, and diorite. The value per ton declined from \$1.23 to \$1.22. Sales of riprap declined greatly, but the value per ton increased 27 cents. Stone used as aggregate and for highways declined moderately, but sales of railroad ballast increased 56 percent. The value per ton for these major uses remained unchanged.

¹ Includes stone sold for base course, all material, roofing granules, and unspecified uses. ² Included under "Undistributed."

MARBLE

In the manufacture of marble blocks much waste accumulates. Some of it is marketed as terrazzo, stucco, or marble flour, and it also finds outlets for the same uses as those to which limestone is applied. It may be sold as agricultural limestone, as a filler, or as road stone or concrete aggregate. The great variation in unit value in different States, as indicated in the accompanying table, is due to the diversity in price among highly refined or commonplace uses.

Marble (crushed and broken stone) sold by producers in the United States in 1944, by States ¹

¹ Includes stone used for agriculture, artificial stone, crushed stone, magnesite, mineral food, poultry grit, riprap, shingles, spalls, stucco, terrazzo, tile, and whitening (excluding marble whitening made by companies that purchase their marble).

² Included under "Undistributed."

LIMESTONE

Sales of limestone were reported to the Bureau of Mines from 44 States in 1944. Because of its wide distribution and relatively low cost of production it is used more extensively than other types of stone in the United States. In 1944 limestone constituted 74 percent of all crushed and broken stone sold (excluding that used for making cement and lime). Metallurgical stone was in strong demand in 1944 because nearly all furnaces were operated at approximately 100 percent of capacity. Agricultural limestone sales increased 30 percent in tonnage compared with 1943. Production was stimulated by the high purchasing power of farmers, by assistance from the Agricultural Adjustment Administration and the War Food Administration, and by Government financing. M. P. R. 386, governing prices of agricultural liming materials, which permitted an advance in ceiling prices when justified by increases in production costs, was revised in October 1944, permitting a more liberal upward adjustment.

Sales of crushed limestone in 1944 were 10 percent lower in quantity and 7 percent lower in value than in 1943. The principal decrease was in stone used for concrete aggregate and for highway construction. Sales for miscellaneous uses are indicated in the second table following.

Limestone (crushed and broken stone) sold or used by producers in the United States in 1944, by States and uses

	15, 545, 430	18, 582, 591	14, 197, 350	18, 209, 842

¹ Includes stone for filler for calcimine, crayons, explosives, foundry facing powder, leather goods, linoleum, paint, paper, phonograph records, plastics, pottery, putty, roofing, rubber, wire coating, and unspecified uses.

² Includes stone for refractory magnesia.

³ Includes stone for acid neutralization, brick glazing, carbon dioxide, ceramics, chemicals (unspecified), concrete blocks and pipes, dye, electric products, motion-picture snow, oil-well drilling, rayon, rice milling, spalls, spray, target marker, and water treatment.

Dolomite (calcium-magnesium carbonate) has a variety of uses. Dead-burned dolomite is used as a refractory lining for metallurgical furnaces, and statistical data on this product (which is closely allied to lime) are given in the chapter on Lime of this volume. Dolomite in the raw state is also used as a refractory, particularly for patching furnace floors. Dolomite is also used as a source of magnesia (MgO) which may be applied to refractory use, employed for heat insulation, or used in various other ways. In 1943 for the first time dolomite was used extensively as a source of magnesium metal. This use has declined owing the cut-back in the metal program.

Sales of dolomite and its primary product of calcination—dolomitic lime—for certain uses are covered in the following table.

Dolomite and dolomitic lime sold or used by producers in the United States for specified purposes, 1943-44

	1943	1944
Dolomite for—		
Basic magnesium carbonate: ¹

¹ Includes flux for copper, gold, lead, zinc, and unspecified smelters.

² Includes flux for foundries, and for cupola and electric furnaces.

Limestone is employed not only in the raw state but also for the manufacture of cement and lime. The latter industries are covered in separate chapters of the Minerals Yearbook. It is of interest, however, to show in one table, as follows, the total tonnage of limestone consumed for all purposes.

Limestone sold or used for all purposes in the United States, 1942-44, in short tons

Use	1942	1943	1944
Limestone (as given in this report) (approximate).....	142,488,000	128,980,000	115,506,000
Portland cement (including "cement rock") ¹	47,657,000	35,867,000	24,148,000
Natural cement ("cement rock") ¹	12,208,000	13,193,000	12,947,000
Lime ²	202,353,000	178,040,000	152,601,000

¹ Reported in terms of cement in chapter on Cement.

² Reported in terms of lime in chapter on Lime.

SANDSTONE

Sales of crushed and broken sandstone declined 13 percent in quantity and 1 percent in value in 1944 compared with 1943. Quartzite (ganister) sold for the manufacture of silica brick dropped 23 percent in quantity and 18 percent in value from the peak of 1943. The average price per ton increased 14 cents. Riprap sales were lower, but stone for concrete aggregate and road building increased substantially. Also the average price per ton was 27 cents higher than in 1943. Sales of railroad ballast and of stone for miscellaneous uses declined greatly.

² Included under "Undistributed."

MISCELLANEOUS STONE

Crushed and broken stone, other than the five principal varieties already discussed, includes light-color volcanic rocks, schists, boulders from river beds, serpentine, and flint. The following table shows sales of these types, by States and uses, in 1944; such sales increased 8 percent in quantity and 19 percent in value over 1943.

Miscellaneous varieties of stone (crushed and broken stone) sold or used by producers in the United States in 1944, by States and uses

¹ Includes stone used for filler (unspecified), ornamental concrete, poultry grit, refractory, road base, roofing granules, stone sand, stucco, and tennis courts.² Included under "Undistributed."³ Chats; figures collected by Joplin (Mo.) office of the Bureau of Mines.⁴ A small quantity of stone included with chats.

FIGURE 3.—Crushed-stone aggregates (concrete and road metal) sold or used in the United States compared with shipments of portland cement, total construction (value), and concrete pavements (contract awards, thousands of square yards), 1932-44. Data on construction and concrete pavements from Bureau of Foreign and Domestic Commerce.

FIGURE 4.—Sales (tons) of fluxing stone and refractory stone, including that used in making lime, as recorded in the chapter on Lime compared with production of steel ingot and pig iron, 1932-44. Statistics of steel-ingot production compiled by American Iron and Steel Institute.

MARKETS

Large quantities of crushed stone are used as aggregate in concrete for both highway and building construction. It is to be expected therefore that crushed stone sales will follow the trend of cement shipments and the area of concrete pavements. These relationships are indicated in figure 3. With completion of nearly all major airfields and military roads, concrete pavement construction in 1944 dropped to the lowest point in many years. The area in square yards was less than half as great as in 1943. Building construction also declined to about one-half of its 1943 volume. Cement shipments were 26 percent less than in 1943. The decline of 21 percent in sales of crushed-stone aggregates was to be expected under these unfavorable conditions.

The metallurgical industries operated almost at maximum capacity during 1944. Pig-iron production of over 61 million tons surpassed its previous high record—that for 1943. The demand for fluxing stone was therefore maintained at a record level. Steel production of over 89 million tons was also the highest on record. To keep furnaces in repair under conditions of forced production placed a heavy burden on suppliers of dead-burned refractory dolomite and ganister for making silica brick. The close relationships of fluxing-stone output to pig-iron production and of refractory stone to steel-ingot manufacture over a period of years are indicated in figure 4.

FUTURE TRENDS

Crushed stone is used principally as aggregate in building construction and highways. As pointed out in the discussion of the future outlook for the dimension stone industries earlier in this chapter, there is an immense backlog of proposed building construction to be undertaken when conditions are favorable. As concrete is an important construction material for all types of buildings, particularly nonresidential, there is prospect of growing markets for aggregates for some years following reestablishment of peacetime conditions.

Highway construction offers more extensive markets for aggregates than building construction. A bill was signed by the President in December 1944 that authorized, but did not appropriate funds for, a postwar Federal expenditure on highways of \$1,673,250,000 as part of a \$3,173,250,000 3-year program. The States must contribute on a 50-50 matching basis to become eligible for the Federal grants. There is fairly definite prospect, therefore, of an extensive market for highway aggregates.

The volume of trade in agricultural limestone depends chiefly on the purchasing power of farmers which will probably be high for several years because extensive markets for food products both at home and abroad are forecast. Sales are governed to some extent also by the firmness of the conviction that applications of lime to the soil are beneficial. This conviction may be strengthened, and the volume of business correspondingly increased, by a recent recommendation of the War Food Administration¹ to the effect that, for best results, the quantity of liming materials used on the land should be increased to nearly three times the tonnage employed in the peak year 1944.

¹ U. S. Department of Agriculture, War Food Administration, A National Policy for Fertilizers and Liming Materials: February 1945, p. 4.

Markets for metallurgical, chemical, and refractory stone depend primarily upon the volume of industrial production. A moderate transition from military to peacetime production was under way shortly after the collapse of Germany, but extensive reconversion is not to be expected until after the fall of Japan. There is, however, an enormous unsatisfied demand for civilian goods which bears promise of high industrial activity following the conclusion of the war emergency.

FOREIGN TRADE²

For security reasons complete annual data covering foreign trade in stone have not been available for publication since 1940. Now that restrictions are lifted, figures for both imports and exports for 1941 to 1944 are presented in the accompanying tables. Exports are never large, and as their destinations are confined chiefly to countries of the Western Hemisphere they have not been affected greatly by the war. Imports from European countries declined very greatly. Granite and quartzite imports remained at relatively high levels, as they originated chiefly in Canada.

Stone imported for consumption in the United States, 1941-44, by classes

SLATE

By OLIVER BOWLES AND M. G. DOWNEY

SUMMARY OUTLINE

	Page		Page
Summary	1272	Review by States and districts	1277
Salient statistics	1273	Postwar outlook	1278
Sales	1273	Foreign trade	1279
Prices	1276		

SUMMARY

Although sales of slate as a whole gained 2 percent in quantity and 3 percent in value in 1944 compared with 1943 the increase was confined almost exclusively to granules and flour. Slate sold as dimension stone (that is, in the form of roofing slate, mill stock, flagstones, etc.) declined 17 percent in quantity and 12 percent in value. The total value of these products—\$1,720,958—was the lowest since 1934.

Roofing-slate sales fell 7 percent in quantity and 5 percent in value below the previous all-time low record of 1943. The average value per square in 1944 was \$9.00, whereas in 1943 it was \$8.75. In the Pennsylvania area sales were 9 percent lower in quantity and 5 percent in value than in 1943. In the New York-Vermont area, however, sales gained 54 percent in quantity and 45 percent in value. In the Buckingham region, Virginia, sales decreased 25 percent in quantity and 24 percent in value.

Sales of mill stock declined 23 percent in quantity and 24 percent in value. Blackboards and bulletin boards and the group of flagstones and related products were the only commodities to gain in sales; all other classifications experienced losses. The output of electrical slate decreased 37 percent in quantity and 42 percent in value from 1943. As building construction of types that employ slate was at a very low ebb in 1944, it is not surprising that structural and sanitary slate dropped 12 percent in quantity and 11 percent in value. Sales of blackboards and bulletin boards increased 8 percent in quantity and 20 percent in value.

Sales of vaults and covers decreased 10 percent in quantity but gained 6 percent in value. The output of billiard-table tops, which made a remarkable gain in 1943, reversed its trend of a year ago, with a decline of 43 percent in quantity and 35 percent in value. Sales of school slates, most of which are exported, declined 45 percent in quantity and 47 percent in value. The market for flagstones, stepping stones, and similar products was somewhat better; sales increased 10 percent in quantity and 22 percent in value.

Statistics of slate granules and flour are included in this chapter although they have little in common with the slate products already mentioned. Granules are, in fact, used in making roofing products that compete in the roofing-slate market, but most of the slate used in the manufacture of granules and flour is unsuited for other slate products. The gains of 5 percent in quantity and 12 percent in value of sales of granules and flour reflect the need for various forms of composition roofing in war housing and in maintenance and extension of other more or less temporary types of war construction. In 1944 the average sales value of granules, f. o. b. mill, was \$9.25 and of flour

\$3.92 per short ton, compared with \$8.71 and \$3.65, respectively, in 1943. Figures for sales of granules made of rock other than slate are given in the chapter of this volume on Stone.

The following table presents the principal statistical data for the slate industry in 1943 and 1944.

Salient statistics of the slate industry in the United States, 1943-44

SALES

Dimension slate.—The term "dimension slate" is applied to blocks or slabs of specified sizes and shapes. It includes all slate products except granules and flour. The following table shows sales of dimension slate for a 5-year period.

Slate (other than granules and flour) sold by producers in the United States, 1940-44

Year	Roofing			Mill stock		Other ¹		Total	
	Squares	Approximate equivalent short tons	Value	Approximate short tons	Value	Approximate short tons	Value	Approximate short tons	Value
1940.....	347,130	127,600	\$2,436,123	17,070	\$935,810	9,780	\$64,435	154,450	\$3,436,368

¹ Includes flagstones, walkways, stepping stones, and miscellaneous slate.

Figure 1 compares sales of roofing slate and mill stock with the number of new dwelling units and the value of new nonresidential building from 1925 to 1944. Roofing slate is used chiefly in residential building and therefore tends to follow the trend of activity in erection of new dwelling units. Other roofing materials compete with slate, and since 1938 slate sales have not kept pace with residential building. It is expected that a postwar revival of home building will rejuvenate the roofing-slate industry.

Mill-stock slate is used most widely in nonresidential building, and sales of mill stock have followed rather closely the trend of such construction since 1925. During the past 3 years sales of slate have been depressed relatively much less than nonresidential building, although both have maintained a low level of activity. A return to

FIGURE 1.—Sales of roofing slate and mill stock compared with number of new dwelling units and value of new nonresidential building, 1925-44. Data on new nonresidential building from Bureau of Foreign and Domestic Commerce and on new dwelling units from Bureau of Labor Statistics.

the more permanent types of peacetime construction will stimulate a wider demand for structural slate.

Figure 2 presents graphically a statistical history of slate over a 30-year period, by uses. It is evident from this figure that the slate industry depreciates greatly during wars and depressions.

Figure 3 presents the history of slate production, by uses, on a quantity basis. The large-tonnage products that have a relatively low unit value assume greater prominence in this chart than in figure 2.

Granules and flour.—Granules are used chiefly in surfacing prepared roofing. Flour, most of which is recovered as a byproduct of the granule industry, is used as a filler in road-asphalt surface mixtures, paints, roofing mastic, linoleum, and various other products. The small gain in sales of granules in 1944 indicates that the demand for composition roofing materials did not recede. Such products are used both in new construction and in maintenance and repair of existing buildings. Sales for a 5-year period are indicated in the accompanying table.

FIGURE 2.—Value of slate sold in the United States, 1915-44, by uses.

FIGURE 3.—Quantity of slate sold in the United States, 1915-44, by uses.

PRICES

The average price of roofing slate, f. o. b. quarry or mill, as reported to the Bureau of Mines, increased 25 cents a square in 1944 compared with 1943. In Pennsylvania, it increased 36 cents a square and in

FIGURE 4.—Prices of slate compared with wholesale prices of building materials in general, 1915-44. Wholesale prices from Bureau of Labor Statistics.

Virginia 6 cents, whereas in the New York-Vermont area it declined 57 cents.

The average value of total mill stock remained unchanged at 35 cents a square foot, although prices of individual products fluctuated considerably. The average value of electrical slate declined 6 cents. Billiard-table tops increased 4 cents, vaults and covers 4 cents, and blackboards 2 cents a square foot, whereas the price of structural and sanitary slate remained unchanged. The sales value of granules increased 54 cents and of slate flour 27 cents a short ton.

Price history.—Figure 4 shows the trend of slate prices compared with prices of all building materials over a 30-year period. During recent years they have been in remarkably close accord.

REVIEW BY STATES AND DISTRICTS

The following table gives sales of slate in 1944, by States and uses.

Slate sold by producers in the United States in 1944, by States and uses

¹ Flaring and similar products, granules, and flour.

² Included under "Undistributed."

³ For details of production in Pennsylvania, see following table.

Maine.—The slate quarries of the Monson district produce electrical slate primarily, with a minor output of roofing slate. Only one company produced in 1944, and the output of both electrical and roofing slate was substantially lower than in 1943.

New York-Vermont.—To maintain necessary confidential treatment of individual company figures, Maine has been included with Vermont in the accompanying table. The total value of slate products sold in New York, Vermont, and Maine was 5 percent more in 1944 than in 1943. Squares of roofing slate sold in Vermont in 1944 declined to less than one-fourth of the number sold in 1942, the latest year for which separate figures may be shown. There were only 11 operators in Vermont in 1944 compared with 26 in 1942. The superior endurance and artistic qualities of the Vermont and New York roofing slates should encourage their wide use in the postwar building era. Production in New York, which consisted chiefly of granules, was considerably higher than in 1943.

Peach Bottom district.—The slate quarries on the Maryland-Pennsylvania border near Cardiff, Md., and Delta, Pa., produced only granules and flour in 1944. Excellent-quality roofing slate is obtainable in this region, but production has been very small during recent years.

Lehigh district.—All the well-known slate products are made in Lehigh and Northampton Counties, Pa., which comprise the most productive slate area in the United States. As separate figures may not be shown for York County it is included with Northampton County in the accompanying table showing detailed figures for Pennsylvania.

The total value of all slate products sold in the Lehigh district in 1944 was lower than in 1943 by the small margin of less than 1 percent. Roofing-slate sales were 9 percent less in quantity and 5 percent in value than in 1943. The following mill-stock products declined in both quantity and value: Electrical (3 percent in quantity and 7 percent in value), structural and sanitary (11 percent in both quantity

and value), billiard-table tops (44 percent in quantity and 38 percent in value), and school slates (45 percent in quantity and 47 percent in value). Blackboards and bulletin boards gained 8 percent in quantity and 20 percent in value, whereas vaults and covers declined 10 percent in quantity but gained 6 percent in value. The value of miscellaneous products (largely granules and flour) gained 9 percent. The "hard-vein" slate of this area is used chiefly for roofing, whereas the "soft-vein" is well-adapted for making blackboards and other structural products in addition to roofing.

¹ Small amount of slate for grave vaults and covers produced in Lehigh County included under Northampton and York Counties.

² York County produced granules and flour only.

Virginia.—Sales of roofing slate, principal product in Buckingham County, declined 25 percent in quantity and 24 percent in value in 1944 compared with 1943. Because of the small number of operators sales of granules and flour may not be shown.

Other districts.—Slate products, chiefly granules and flour, were produced in Montgomery County, Ark., near Glenwood; near Placerville, Eldorado County, Calif.; and in Bartow County, Ga., near Fair Mount.

POSTWAR OUTLOOK

The degree of prosperity attained by the slate industry in the years immediately following the war will depend chiefly on the volume of new residential construction. This type of building was at a very low level in 1944 and will so continue until the war emergency has passed. Rehabilitation of the slate industry is conditioned primarily on cessation of major hostilities. Even when the war emergency is over some time must elapse before a substantial increase in slate production may be expected. The length of this period will depend upon the promptness with which residential building is resumed after the close

of the war. Several months may elapse after the green light is flashed, permitting resumption of general building activity, before such bottlenecks as hardware and plumbing-fixture needs will be cleared.

A vast backlog of residential building exists. The F. W. Dodge Corporation reports a total of more than \$1,100,000,000 as the value of planned residential postwar construction; but early in 1945 most of it had not reached the design stage. The slate industry has the prospect of benefiting in a large way from this program. Unfortunately, however, that industry will experience considerable difficulty in weathering the unparalleled depression of the war years. Some quarries will be abandoned permanently because they cannot be dewatered and reconditioned profitably. Consequently, the industry may not be in a position to take full advantage of a broad expansion in market demands.

FOREIGN TRADE ¹

Because of Government restrictions, recent figures on imports and exports have not been published. However, these restrictions have been relaxed to the extent that detailed data for 1941 and 1942 may now appear.

Imports.—Imports of slate into the United States are very small. Their value for the 5 years 1938–42 is indicated in the following table.

Slate imported for consumption in the United States, 1938–42, by countries

SUMMARY

In harmony with the general trend in construction activity, the output of sand and gravel declined to a prewar level in 1944.

Industrial sand rode the crest of war production to a new record; but building and paving materials, which constitute the bulk of the sand and gravel tonnage, were caught in a declining period following the height of war construction. Labor problems, decreasing tonnage, and shortage of supplies made production increasingly difficult. A few price increases were authorized by the Office of Price Administration, but on the average unit values were slightly lower than in 1943. Commercial operations produced over three quarters of the total tonnage as Government-and-contractor output declined to the lowest point since 1935.

FIGURE 1.—Total production of sand and gravel in the United States, 1905-44.

POSTWAR PROSPECTS

Sand and gravel producers expect a large market after the war. If financial conditions are favorable, home and industrial building can reach major proportions. Road maintenance has been more or less neglected for several years. Networks of new highways and many new dams have their advocates. Although such projects have

many obvious advantages the whole program draws its strongest support from the fact that it can serve as a means of maintaining high employment. Some of the money has already been earmarked for specific purposes, but many financial obstacles remain to be overcome.

Sand and gravel sold or used by producers in the United States, 1943-44, by commercial and Government-and-contractor operations and by uses

³ Includes some sand used by railroads for fills and similar purposes as follows—1943: 170,372 tons valued at \$23,974; 1944: 226,965 tons, \$57,060.

⁴ Includes ballast gravel produced by railroads for their own use as follows—1943: 7,661,118 tons valued at \$1,967,362; 1944: 9,097,590 tons, \$2,896,111.

⁵ Includes some gravel used by railroads for fills and similar purposes as follows—1943: 1,176,243 tons valued at \$266,318; 1944: 1,605,789 tons, \$308,780.

⁶ Approximate figures for States, counties, municipalities, and other Government agencies directly or under lease.

Industrial sands have only remote prospects of greatly exceeding 1944 tonnages immediately after the war. Neither is there any likelihood of collapse of their markets. They serve the manufacturing industries and will reach whatever level of output industrial production attains.

PRODUCTION

In 1944 production of sand and gravel was about 17 percent lower than in 1943.

By comparison with the record of over 300,000,000 tons set in 1942, production in 1944 was not very impressive, but by prewar standards the total was respectable—higher than the production level in 1938. The decline was primarily in the output of building and paving materials. As a class the industrial sands attained a new record, and ballast tonnage was greater than in 1943. Because stocks of sand and gravel are comparatively small and constant, production virtually equals sales. The two terms are used interchangeably in this report

Sand and gravel sold or used by commercial and Government-and-contractor producers in the United States, 1940-44

Year	Sand		Gravel (including railroad ballast)		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1940.....	78,674,000	\$45,332,000	159,634,000	\$65,356,000	238,308,000	\$110,688,000
1941.....	103,835,000	62,152,000	184,880,000	85,055,000	288,715,000	147,207,000
1942.....	107,371,000	74,443,000	196,975,000	114,057,000	304,346,000	188,500,000
1943.....	82,053,000	62,263,000	152,011,000	90,530,000	234,064,000	152,793,000
1944.....	68,978,000	54,054,000	125,805,000	71,110,000	194,783,000	125,164,000

California was again the leading producing State, followed by Illinois, Michigan, and Ohio in that order. The ranks of the States producing over 10,000,000 tons had dwindled from 9 in 1942 to 4 in 1944. Details of output in 1944, by States and uses, are presented in the following tables:

Sand and gravel sold or used by commercial and Government-and-contractor producers in the United States in 1944, by States

^a Included under "Undistributed."

^b Includes items entered as "i."

^c Includes 482,293 tons of blast sand valued at \$1,228,744.

^d Includes 40,486 tons of ballast sand valued at \$10,263, produced by railroads for their own use.

^e Includes 286,965 tons of sand valued at \$57,060, used by railroads for fills and similar purposes.

^f Includes 9,097,560 tons of ballast gravel valued at \$2,896,111, produced by railroads for their own use.

^g Includes 1,605,789 tons of gravel valued at \$308,780, used by railroads for fills and similar purposes.

Government-and-contractor production.—As shown in the accompanying chart, during the depression Government-and-contractor production of sand and gravel became a very large factor in the industry. When defense and war activities displaced peacetime public projects its tonnage began to decline, and this trend continued through 1944. Whereas in 1939 Government-and-contractor production of

sand and gravel constituted 48 percent of the total output, by 1944 it had shrunk to 23 percent. The contributions of municipalities and counties have been fairly well maintained, but in 1944 the States were only about half as active as before the war, and Federal organizations reported only about one-tenth as much as in 1939.

In 1944 States reported 42 percent of the total, counties 42, municipalities 3, and other agencies 13.

As compared with 56 percent in 1943, contractors furnished only 37 percent of the total tonnage in 1944. The average value of Government-and-contractor production was 6 cents lower.

FIGURE 2.—Sand and gravel sold or used in the United States by commercial and Government-and-contractor producers, 1930-44.

Sand and gravel sold or used by Government-and-contractor producers in the United States, 1940-44, by uses

METHOD OF TRANSPORTATION

Shortages of tires, gasoline, and truck replacements have given the railroads an opportunity to carry a higher percentage of the sand and gravel tonnage than before the war. On the other hand, shippers found that railroad cars were also at a premium, and even though total sales had declined deliveries were often delayed. Although railroads handled more than half of the output of commercial plants trucking is still the predominant method of transportation owing to its domination of Government-and-contractor operations. Waterways carry only a minor fraction of the national total, but in many localities their facilities are the most economical and convenient.

Sand and gravel sold or used by commercial producers in the United States, 1943-44, by methods of transportation¹

Method of transportation	1943		1944	
	Short tons	Percent of total reported	Short tons	Percent of total reported
Truck.....	67,475,351	42.4	58,210,087	42.4
Rail.....	77,700,913	48.8	68,809,663	50.1
Waterway.....	13,974,693	8.8	10,359,959	7.5
Total reported.....	159,150,957	100.0	137,469,709	100.0
Percent of total commercial production covered.....		90.0		91.0

¹ For practical purposes the entire output of Government-and-contractor operations commonly is moved by truck. Including Government-and-contractor production, sand and gravel moved as follows—1943: Truck 58 percent, rail 36 percent, and waterway 6 percent; 1944: Truck 56 percent, rail 38 percent, and waterway 6 percent.

DEGREE OF PREPARATION

A large proportion of the sand and gravel produced in commercial plants is screened or otherwise prepared to meet specifications. On the other hand, the output of Government-and-contractor operations has a high percentage of unprepared material direct from the deposit. Washing and screening are inexpensive processes, but processing of any kind adds considerably to the cost of low valued products. Consequently, as shown in the accompanying table, output from commercial plants has a higher average unit value than has that from Government-and-contractor operations. Of the total sand and gravel

production in 1944, 71 percent was classified as prepared—the same ratio as in 1943.

Sand and gravel (prepared or unprepared) sold or used by producers in the United States, 1943-44, by commercial and Government-and-contractor operations

	1943			1944

Grand total.....	234,064,000	-----	.65	194,783,000	-----	.64

SIZE OF PLANTS

Plant size has returned substantially to the prewar pattern. From 87,000 tons in 1942 the average output of commercial plants declined to 62,000 tons in 1944. The number producing over 500,000 tons dropped from 76 to 30, and they contributed only 17.1 percent of the total tonnage as compared with 29.2 percent in 1942. The 51.1 percent that sold less than 25,000 tons apiece furnished only 7.1 percent of the total tonnage. More than half the plants are small, but the bulk of the output comes from those making more than 100,000 tons annually. Details of output, by size groups, in 1943 and 1944 are given in the following table.

Comparison of number and output of commercial sand and gravel plants in the United States, 1943-44, by size groups¹

Size group, in short tons	1943				1944

¹ Plants operated by or for States, counties, municipalities and other Government agencies are not included; also not included are approximately 165 railroad plants with an output of 9,036,000 tons of sand and gravel in 1943 and 180 plants with an output of 11,031,000 tons in 1944.

² Includes a few companies operating more than 1 plant but not submitting separate returns for individual plants.

PRINCIPAL TRENDS

Sand and gravel for construction.—As shown in the accompanying chart, construction indexes continue to lead sand and gravel down, indicating a further decline in production for 1945. As the war progresses, construction reaches the doldrums, because the need for war construction declines and components for peacetime projects cannot be released in sufficient quantity. Little relief is expected until the end of the war.

FIGURE 3.—Value of sand and gravel production compared with total construction (contract awards, value) and concrete pavements (contract awards, thousands of square yards) in the United States, 1933-44. Data on construction and concrete pavements from Bureau of Foreign and Domestic Commerce.

Industrial sands.—Serving the manufacturing rather than the construction industries, the industrial sands fared very well in 1944. Metal working was near capacity, consumption of glass sand increased substantially, and, although the tonnage of a few types declined somewhat, the output of industrial sands as a class attained a new record. Production of these sands is expected to continue at a high rate until the end of the war and possibly thereafter. Figure 4 shows the quantities of the various types of industrial sands produced during the past 29 years.

EMPLOYMENT AND PRODUCTIVITY

Commercial sand and gravel producers had difficulty in finding enough manpower to supply even the depleted demand. Total employment dropped to about 22,000 and on the average the men worked 9 hours per day. Considering the labor turn-over and decline in sales, productivity has been well-sustained. Although not as high as in 1941 and 1942, output per man-hour in 1944 compared favorably with prewar figures. The reports of operators who produced four-fifths of the total commercial tonnage are summarized in the accompanying tables.

FIGURE 4.—Production of industrial sands in the United States, 1916-44.

PRICES

After advancing continually since 1940 the average value of sand and gravel declined slightly in 1944. Details of valuation are shown in the summary table at the beginning of this chapter.

Sand and gravel prices were controlled by the provisions of Maximum Price Regulation 188. After demonstrating the essentiality of their production and the need for relief, operators in Los Angeles, Miami, St. Louis, and a few other areas were authorized by the Office of Price Administration to raise prices. However, no general price increases were authorized, and competition for a declining volume of business also tended to control and in some cases reduce prices.

NEW DEVELOPMENTS

The practice of placing a carefully vented granular subbase course under all types of pavement to provide drainage has been very successful in preventing rupture from freezing or pumping, and it is being adopted more widely.¹

Producers are concerned over the trend toward requirement of higher percentages passing 50- and 100-mesh in specifications of concrete aggregates. In one area only 50 percent of the plants had enough fines in their deposits to meet proposed specification changes that would have required 10 to 30 percent minus 50-mesh and 2 to 10 percent minus 100-mesh.² To meet the new conditions, some companies are turning to crushing, and some are admixing fines obtained from other locations. Many companies that have ample fines in their pits find that their washing systems must be modified to retain the proper quantity. As entrained air acts somewhat like a fine aggregate it is possible that in the future the use of air-entraining compounds will reduce the need for higher proportions of mineral fines.

² Rock Products, vol. 47, No. 9, September 1944, p. 74.

FOREIGN TRADE.

Compared with the quantity of sand and gravel used in the United States, foreign sales and purchases are negligible. However, by most standards the tonnage is considerable.

Owing to wartime restrictions on publication of foreign trade statistics, the Sand and Gravel chapter has not contained current figures since 1941. As these limitations have now been liberalized the accompanying table shows the record of imports during the past 10 years. Before the war Belgium had a market for glass sand on the West coast, but in 1940 this movement was interrupted. In 1944 over 99 percent of all imports came from Canada.

Exports of sand and gravel have not been separately classified by the United States Department of Commerce since 1939, but before then they commonly ranged between 25,000 and 100,000 tons a year. A summary of exports is given in Minerals Yearbook, 1942.

Sand gravel imported for consumption in the United States, 1935-44, by classes

³ Less than 1 ton.

BLAST-FURNACE SLAG

In 1944 output of commercialized blast-furnace slag totaled 12,405,992 short tons, 25 percent less than the 16,507,607 tons reported in 1943. Sales of air-cooled slag declined 24 percent, and the average value per ton of screened increased 1 cent, whereas unscreened was 1 cent lower than in 1943. These statistics are based on a canvass, conducted by the National Slag Association, of the 32 companies that prepare blast-furnace slag for commercial use.

Practically all of the commercial production is east of the Mississippi River, chiefly at steel centers located in Ohio, Alabama, Pennsylvania, and Illinois. Shipments, however, are made into all States east of the Mississippi except some of the New England States outside the economic range of sources of supply. Shipments of slag are made by railroad, truck, and waterway. The accompanying tabulations show the pattern of distribution during the past 4 years.

The average shipping range of blast-furnace slag in 1944 was 61 miles by rail, 15 by truck, and 125 by waterway. In most instances shipments did not exceed 100 miles by railroad, 30 by truck, and 250 by waterway.

Rail.....	55	52	56	55
Truck.....	43	47	44	44
Waterway.....	2	1	(?)	(?)

¹ National Slag Association.² Less than 0.5 percent.

Details of the tonnage and values of slag consumed in the various uses are shown on an accompanying table. With the decline in construction activity since 1942, consumption in buildings and roads has fallen. On the other hand, railroads have faced a huge track-maintenance problem that could not be ignored. Insufficient labor has been a limiting factor, but means have been found to place nearly 3,000,000 tons of slag ballast annually during the past 3 years.

The quantities consumed in the manufacture of mineral wool and lightweight aggregates have increased since 1942, and promotion of agricultural slag has met some success. Finely ground slag is said to have value as a liming material and as a source of essential minor fertilizer compounds.

When slag is tapped from the blast furnace some iron also escapes through the slag notch. By hand picking and magnetic pulleys this metal is separated during crushing and screening at the slag plant; producers reported that 114,790 tons of iron were recovered and returned to the furnaces in 1944. The yield was about 1.2 percent or approximately 24 pounds of iron per ton of slag processed.

Not including those assigned to administrative, office, and sales activities 1,400 plant and yard employees were engaged in the production of commercial slag in 1944.

SUMMARY

Production of crude gypsum in 1944—3,761,234 short tons—was 3 percent less than output in 1943 and 8 percent less than the average annual output during 1939–42. The decrease reflected the continuing impediments to construction. Calcined gypsum output was 8 percent less in 1944 than in 1943 and 28 percent less than the average annual production for 1939–42. Sales of uncalcined gypsum were 14 percent lower in 1944 than in 1943 and 9 percent lower than during the 1939–42 period.

Although public and private construction dropped 54 percent in 1944 as compared with 1943 (according to the United States Department of Commerce), shifts in the gypsum use pattern and substitution of gypsum board for scarce 1-inch lumber enabled the gypsum products industry as a whole to operate at near 1943 levels. The decline in construction did not materially affect sales of base plasters and gypsum lath. Demand for these items has been maintained in the last 2 or 3 years only at the volume necessary for repairs and a small amount of permissive construction and may be expected to remain at this level until general restrictions are removed from regular home building. Sales of lath and of base plaster in 1944 were about one-third of prewar volumes. Despite construction curtailments, wall-board sales were well-maintained in 1944 and indeed were considerably higher than prewar output, owing to substitution in construction outlets formerly dominated by 1-inch soft lumber. Expanding requirements for pattern-making and molds in machine shops and foundries maintained industrial sales of calcined gypsum at a high figure and partly offset declines in pottery and dental and orthopedic plasters. A 32-percent decline in the production of portland cement in 1944 caused an almost identical drop in sales of uncalcined gypsum for cement retarder. Curtailment of this market was partly offset by increased sales of agricultural gypsum.

War Production Board Conservation Order L-41 has restricted all types of construction since April 1942, and amendments during 1944

further tightened farm construction. Price control of gypsum products was continued under Maximum Price Regulation 188 of the Office of Price Administration, based on March 1942 levels. To help relieve a shortage of gypsum board in Arizona, California, Oregon, and Washington for use in Government projects, the agency since September 18, 1943, has permitted dealers in the States named to buy gypsum wallboard, lath, and sheathing from mills as far east as Ohio at mill price plus added freight. (Gypsum board is ordinarily sold on a delivered basis.) This provision, extended several times since its inception, expired January 1, 1945.

Imports of crude gypsum, nearly all from Nova Scotia and New Brunswick, Canada, were of the same order as in 1942 and 1943. Receipts in 1944 were about one-fourth of 1941 imports. Very little shipping space has been available.

Board plants operated at 67 percent capacity in 1944 compared with 78 percent in 1943 and 82 percent in the last four months of 1942.

² Revised figure.

³ Excludes byproduct gypsum.

⁴ Made from domestic, imported, and byproduct crude gypsum.

Gypsum products for export are normally sold by plants situated in eastern metropolitan centers, on a delivered price basis derived from the f. o. b. plant price at the nearest metropolitan mill plus an average trucking or shipping charge within the delivered area. The shortage of crude gypsum in the East has curtailed the amount of board available for Lend-Lease, and to draw on production farther west, the Office of Price Administration in Amendment 70 to Order A-1 under Maximum Price Regulation 188, February 15, 1945, permitted producers in eight specified States to add actual transportation costs to their f. o. b. plant ceiling prices for wallboard, lath, sheathing, and laminated gypsum products destined for export from Atlantic ports on Government or Lend-Lease orders.

Gypsum bagging was standardized to 2-, 5-, 10-, 25-, 50- and 100-pound bags by the War Production Board in Limitation Order L-279. As amended August 8, 1944, the order limits the use of bags to specified agricultural products, chemicals, and building materials, including gypsum plaster.

Court trial of the civil action by the United States Department of Justice against 7 gypsum companies and officials on charges of violating the Sherman Antitrust Act opened November 19, 1943, and was decided in 1944 in favor of the defendants. The Government urged that the licensing agreements of the U. S. Gypsum Co. with other members of the industry were beyond the scope of the monopoly of

FIGURE 1.—Trends of new crude supply, domestic crude mined, and production of calcined gypsum, 1940-44, by quarters.

the patents licensed—particularly the Roos foam board patents—and asked that the patents be voided and the licenses dissolved. The court refused to do either.¹

The labor shortage in the industry was more severe than in 1943, when the War Manpower Commission certified the mining of gypsum and the production of gypsum boards to the list of activities essential to the war. According to the United States Department of Labor, 4,000 persons were employed in gypsum-product plants in February 1945 compared with 4,600 in February 1944 and 4,300 in February 1943. Average monthly employment in the gypsum products industry in 1944 was 84.0 percent of employment in 1939 compared with 92.0 percent in 1943. Overtime was considerable in 1944, as indicated by an average monthly wage-earner pay-roll index of 146.4 compared with 100 in 1939.

¹*United States v. U. S. Gypsum*, 53 Fed. Sup. 889 (Dist. Ct. Dist. Col., 1943).

POSTWAR OUTLOOK

A high level of activity in the gypsum industry is indicated for the postwar era. Building curtailment during the war has shelved a large volume of construction projects, both public and private, according to surveys made by various fact-finding agencies. Gypsum products doubtless will be used in the same capacity as in prewar years, except that gypsum board may find a wider application in farm construction than formerly. The industrial plaster group probably will continue at high levels both before and after reconversion. The new techniques developed with plaster models, patterns, and castings in the airplane industry may be utilized in retooling automobile and other mass-production plants. Renaissance of the auto industry also will mean expanded sales of plasters used to bed auto windshields and windows during polishing.

DOMESTIC PRODUCTION

Mine output of crude gypsum was 3 percent less than in 1943. Production declined in Iowa, New York, Texas, and other States but increased in California, Michigan, and Nevada. Active operations totaled 49, comprising 22 underground mines, 19 open quarries, and 8 mine-quarry combinations. The average mill value of run-of-mine gypsum was \$1.72 a short ton, an advance of \$0.18 over 1943

CALCINED PRODUCTION AND PROCESSING EQUIPMENT

The calcined production in 1944 was obtained from 47 active plants distributed through 20 States. Active calcining equipment in these plants comprised 190 units. The average mill value of calcined gypsum, which is a "transfer value" assigned by producers, increased 9 cents over 1943 to \$5.86 in 1944.

¹ Includes rotary and beehive kilns and grinding-calcining units, 1942-43; rotary and beehive kilns, grinding-calcining units, and hydrocol cylinders in 1944.

² 1942: 1 calcining plant each in Arizona, Connecticut, Florida, Georgia, Indiana, Massachusetts, New Hampshire, Oklahoma, Pennsylvania, South Dakota, and Vermont; 2 each in Colorado, Kansas, Montana, Nevada, New Jersey, Ohio, and Virginia; 4 calcining plants in Utah. 1943: 1 calcining plant each in Connecticut, Florida, Georgia, Indiana, Massachusetts, New Hampshire, Oklahoma, South Dakota, Vermont, and Wyoming; 2 each in Colorado, Kansas, Montana, Nevada, New Jersey, Ohio, Utah, and Virginia. 1944: 1 calcining plant each in Connecticut, Florida, Indiana, Massachusetts, Oklahoma, South Dakota, and Vermont; 2 each in Colorado, Kansas, Montana, Nevada, New Jersey, Ohio, Utah, and Virginia.

Thirty-five board plants operated at 67 percent of capacity in 1944 compared with 78 percent in 1943 and 82 percent the last 4 months of 1942. Capacity data are upon a time-utilized basis, in which 100 percent equals full operation for 85 percent of the total number of hours in each month. Highest activity was reached in February, lowest in July. Over-all activity of machines in Atlantic tidewater plants was well below that of machines in plants processing domestic crude.

DISTRIBUTION OF SALES BY USES

Percentage-wise the principal gypsum products maintained about the same order of sales in 1944 as during 1943. Figure 2 shows shifts in the sales pattern during the war, compared with sales in 1928. Of particular interest are the increasing importance of lath and the decline in building-plaster sales in 1940 and 1941 as compared with 1928, and also the greatly increased board sales, which began to level off only in 1944.

In figure 3, lath and board sales are correlated with the Dodge Corporation figures for floor area of construction in 37 States east of the Rocky Mountains. Although lath reached a wartime low in 1944, sales were not as low as the low construction curve would indicate. Probably most lath was sold for maintenance and repair and, with plaster, as a lumber substitute in partitions. Board sales were also higher proportionately than construction activity might predict and indicated wide replacement of construction lumber.

The year 1944 marked the 50th anniversary of gypsum board, which when first produced consisted of three layers of gypsum and

FIGURE 2.—Percentage distribution of total sales value, f. o. b. plant, of gypsum products in 1928 and 1940-44, by groups of products.

four alternate layers of wool felt paper and was used as lath. Gypsum wallboard proper was developed about 1912 and gypsum sheathing in 1925. These wallboards were made for interior use but could be used on the exterior if protected from the weather with wood siding, stucco, or brick veneer. When the war shortage of lumber began to press in 1942, replacements of waterproofed laminated gypsum board were developed for short-span roof decks and exterior siding, available in 1-, 1½-, and 2-inch thicknesses. This board is not load-bearing but weathers well if properly waterproofed and protected from standing water.

Gypsum board has been used increasingly in the construction and repair of farm buildings during the lumber shortage. Waterproofed sheathing and laminated board have been used in constructing chicken

houses, brooders, hog houses, and other service buildings. Since the beginning of the war, gypsum board has been introduced as a ceiling under barn haymows to inhibit the spread of hay fires.

Surfacing gypsum wallboard with aluminum to reflect radiant heat and thus increase insulating properties is not new. However, only recently has aluminum foil been used as a vapor barrier to prevent accumulation of water vapor in the exterior walls. The foil faces the air space.

It is reported that the Industrial Commission of Wisconsin has approved as a wartime measure the use of gypsum roof deck units on

FIGURE 3.—Trends in sales of gypsum lath and wallboard and other board (includes wallboard, laminated board in terms of component board, and sheathing) compared with Dodge Corporation figures on floor area of residential and nonresidential building, 1929-44.

barns, garages, warehouses, and lumber sheds, for spans of 16 and 24 inches on pitched roofs.²

Haddon, a British writer, noted that plaster ceilings in Britain keyed to gypsum lath had stood up better in the blitz than ceilings keyed to wood lath.³

Sales of uncalcined gypsum for portland-cement retarder were less than half the record sales in 1942, and this severe decline was only partly offset by record sales of agricultural gypsum—"land plaster." Most of the consumption was in California, where it is used to neutralize black alkali soils and to supply sulfur. Considerable quantities also are used on the peanut crops in the Southeastern States.

Sales of industrial plasters as a group reached record levels in 1944 owing to the demand for plaster models and patterns in tool shops. Sales in the plate-glass and terra-cotta subgroup were higher than in 1943, but full recovery cannot be expected until automobile wind-shields and windows are again made in mass quantities.

PRICES

The prices of gypsum products were frozen at March 1942 levels by Maximum Price Regulation 188 of the Office of Price Administration, with amendments as noted earlier in this chapter. About three-quarters of the gypsum produced is calcined by the producer and does not enter the open market. The remainder is sold largely as portland-cement retarder and agricultural gypsum. The average value for retarder sales was \$2.10 a short ton and for agricultural sales \$3.38. Average prices of calcined products increased over those of 1943, on the whole. Percentage deviations are noted in a preceding table.

RECENT DEVELOPMENTS

Schleede has summarized and illustrated the uses of gypsum industrial plasters in making patterns and models.⁴ A plaster "mock-up" of the P-63 fighter plane, built on an H-beam and reinforced with templates, has been the source of shell casts for tools from which the surface plates are stamped. The dimensions of the mock-up have not changed in the past 2 years. Over 2 tons of plaster were

⁴ Schleede, F. H., *Patterns of Gypsum Cement*, part 1: The Foundry, vol. 72, No. 14, October 1944, pp. 76-77, 224, 226, 228; part 2, vol. 72, No. 11, November 1944, pp. 90, 186, 188, 190, 192, 194.

consumed in this one model.⁵ A large proportion of pottery molds are made from gypsum calcined under pressure, which gives a very dense mold. Dailey has found that if all the relatively coarse particles (plus 75 microns) are removed from the pressure-molded plaster, it may be diluted with as much as 70 percent of regular plaster without adversely affecting its use. If the coarse particles are not removed when the dense material is mixed with regular plaster, differential wear occurs, the regular plaster wearing away first, leaving protrusions of the harder plaster which mar the surfaces of the molded pottery.⁶

The shortage of tinfoil has suggested changes in dental molds. Heretofore the plaster mold for a plate has been covered with tinfoil as contact between plaster and plate tends to blanch the latter during curing. Gold⁷ found that blanching does not occur if certain organic ingredients are added to the dry mix. On the other hand, it has been recommended that the mix formula remain unchanged but that the tinfoil be replaced by a sprayed water-soluble silicate film.⁸

Research on more reliable plate-glass bedding plasters was carried forward. Lime acts as a wetting agent and reduces expansion in such plasters, and to save time at the plate-glass mill the lime is generally added to the mix at the plaster plant. However, after the plaster is bagged, the lime tends to recarbonate on storage, and then it delays setting. Wiss proposes to eliminate lime and retain its advantages by the following formula: Calcined gypsum 96.9 to 97.3, portland cement 2.5, potassium sulfate 0.1 to 0.5, and calcium chloride 0.1 percent.⁹ Gardner suggests retaining the lime but stabilizing the setting time by adding portland cement and an accelerator: Calcined gypsum 81 to 98.9, lime 0.1 to 8.0, portland cement 1.0 to 8.0, and accelerator 0.01 to 3.0 percent.¹⁰

FOREIGN TRADE¹¹

Imports of crude gypsum during 1944 were mostly from Nova Scotia and New Brunswick, Canada. The small quantity listed as originating in the Dominican Republic was consumed in Puerto Rico. Most of the Nova Scotia receipts were landed at New York and a smaller quantity at Boston. About 15,000 tons were entered in the Virginia and Georgia customs districts for use as peanut fertilizers.

Exports of wallboard were much higher in 1944 than during the previous year, and but for the labor shortage on the Atlantic seaboard they might have been even greater. The labor situation was a little better in the gypsum plants in the Ohio area, and the Office of Price Administration ruling in February 1945—that gypsum board from that area could be sold to Lend-Lease agencies at mill price plus freight to Atlantic port—may increase exports in 1945.

WORLD PRODUCTION

Very few production data by countries have been available since 1939, and the only figures available for 1944 are for the United States, Canada, Cuba, and Switzerland. Output in the United States, represented approximately one-third of the world production and is estimated to be about three times that of each of the next ranking countries—Germany and the United Kingdom. Other countries with important output, in probable order of tonnage, are Spain, France, and Russia.

SUMMARY

The lime industry in 1944 experienced remarkably little change compared with 1943. Sales of "open-market" lime totaled 6,473,563 short tons, receding 2 percent from the all-time high of 1943. The average price per ton advanced 8 cents. Quicklime represented 80 percent and hydrated lime 20 percent of the total, the same as in 1943. Sales of agricultural and refractory lime gained slightly, but building lime and that used in the chemical and processing industries experienced small declines. The most difficult problem with most operators was shortage of labor.

The steady decline in the number of producers, as indicated in the accompanying table of salient statistics, continued in 1944, with a drop of 35 in the number of active plants. Foreign trade data for 1943 and 1944, heretofore regarded as confidential because of military restrictions, may now be released, and the figures are included in this table. Foreign trade in lime is of minor importance.

The supply situation with respect to chemical lime was somewhat critical throughout the year. Threatened shortages were due partly to increased demands and partly to impediments to production, the chief of which were curtailment of industrial gas supplies, poor quality of fuel, and inadequate labor. Deliveries were impeded at times by shortages of cars. Allocation was not deemed necessary, but consumers were urged to place orders well in advance of delivery dates.

The most striking changes in chemical and industrial uses were the substantial increase in the requirements of the calcium carbide industry and the large decline in the quantity needed for ore concentration. However, throughout the whole field of industrial uses the gains and losses were nearly in balance.

The permitted maximum prices of building and chemical lime were continued through 1944 at the March 1942 level as fixed by Maximum Price Regulation 188. Amendments to Order A-1 of the regulation permitted upward revision of prices where shortages occurred. An increase of 45 cents a ton for certain producers of high-calcium lime in Ohio was authorized in April 1945, and an increase of 65 cents a ton was authorized for Virginia, North Carolina, South Carolina, Georgia, Alabama, Tennessee, Mississippi, and Louisiana in May 1945. These authorizations did not affect prices of agricultural lime, which were controlled by Maximum Price Regulation 386.

Late in 1944 an amendment to Order A-1, M. P. R. 188, was promulgated, permitting sale by one producer to another at a price exceeding the established maximum, provided the excess in price was absorbed by the buying producer.

Salient statistics of the lime industry in the United States, 1925-29 (average), 1935-39 (average), and 1942-44

FUTURE TRENDS

Lime has a multitude of chemical uses, involving neutralization, precipitation, causticization, solution, dehydration, absorption, saponification, and catalysis. It either forms a part of, or enters into, the process of manufacture of innumerable products, and for most of its uses substitution of some other material is difficult or impossible. Because of its many and varied applications the growth of the chemical lime industry has in general followed the trend of industrial development. The abrupt termination of major hostilities in Europe on May 8, 1945, reawakened a latent demand for many industrial products that have been in short supply or entirely lacking for several years. Reconversion to peacetime industrial activity doubtless will take place as rapidly as is consistent with maximum military effort in the Pacific, and following a victorious conclusion of that campaign the manufacture of a multitude of machine products to satisfy deferred demands may be expected. Chemical lime will play an important part in any broad industrial program.

The predominant types of military construction that characterized the war years employed minimum quantities of mortar and plaster; hence, building-lime sales have reached a low ebb. An enormous program of private construction, deferred because of wartime restrictions and impediments, awaits initiation when favorable conditions—now in prospect—arrive, and when this great building program materializes the market for building lime will automatically broaden.

Agricultural liming materials have been in heavy demand to promote maximum output of farm products. Lime sales increased somewhat in response to this demand, but agricultural limestone responded more vigorously. The urgent need for chemical lime in war industries during 1943 and 1944 no doubt reduced the available supply of agricultural lime. Restricted food supplies in the United States and serious shortages abroad are strong incentives for increasing farm production, and such increase will call for larger supplies of liming materials.

PRODUCTION

Production in 1944 increased for agricultural and refractory uses but declined for building use and for application in the chemical and processing industries. As stocks of lime are small, the sales given in the following table are regarded as equivalent to production of "open-market" lime.

Lime sold by producers in the United States, 1943-44, by types and major uses

¹ Selling value, f. o. b. plant, excluding cost of containers.

² Includes lime used by producers (captive tonnage) as follows—1943: 434,571 tons, valued at \$2,457,785; 1944: 432,166 tons, \$2,570,544.

³ Less than 1 percent.

CAPTIVE TONNAGE

The captive tonnage (lime used by producers in their own operations) included in the figures for "open-market" lime in 1944 totaled 432,166 short tons valued at \$2,570,544. This total comprised 7,518 tons for masonry mortars, 318,276 tons for metallurgical uses, 18,368 tons for minor chemical uses, and 88,004 tons of refractory lime.

Captive tonnage presents a difficult statistical problem. An overall picture of total lime used in industry is desirable, but the figures most useful to the lime industry and to others who study lime manufacture from the standpoint of a commercial enterprise are those of "open-market" lime that freely enters trade. For any break-down of lime by uses, or by movement between States, it is highly desirable to keep the noncommercial figures separate from the commercial. Furthermore, any study of prices or unit values would be meaningless if the captive lime were combined with the open-market lime, because any value given to the former would be purely arbitrary.

For lime that is made and used in the same plant, calcination is merely one step in a series of chemical processes, and the lime loses its identity as lime in many instances, almost immediately after calcination. Accordingly, the captive tonnage if reported as limestone is included in the statistics on stone, and if reported as lime it is generally converted to its equivalent of limestone and also included in the statistics of stone. The limestone used to produce this captive tonnage has been included since 1921 in the chapters on Stone of Minerals Yearbook and its predecessor, Mineral Resources of the United States.

A figure for the total quantity of lime used in industry may be obtained by combining the chemical lime figures given in this chapter with those represented by limestone recorded in the chapter on Stone, as limestone that has been converted into lime in plants that use it in their own processes. The total chemical lime recorded in this chapter amounts to 4,196,383 tons. Lime produced from stone consumed in the alkali, carbide, glass, magnesium metal, magnesium carbonate, paper, and sugar industries as listed in the chapter on Stone amounted to approximately 4,757,800 tons. Hence, the total open-market and captive lime was about 8,954,183 tons in 1944. Except for the small tonnage of captive lime applied to special uses for which complete coverage is obtained in the lime reports, the detailed statistics that follow are confined to "open-market" lime.

PRODUCTION BY STATES

In 1944 lime was produced at 210 plants in 36 States and 2 Territories. Production by States and Territories, in so far as the figures may be segregated, is indicated in the following table.

¹ Excludes bleach used in paper mills.² Included under "Undistributed."³ Includes chocolate, cocoa, fruit juices, phosphate baking powders, and unspecified food products.⁴ Includes flotation, cyanidation, bauxite purification, and magnesium manufacture.⁵ Includes mold coating and unspecified.⁶ Includes bleach used in paper mills.⁷ Includes alcohol, bromine, calcium carbonate (precipitated), cement manufacture, dicalcium phosphate, photographic supplies, polishing compounds, retarder, rock wool, sulfur, tobacco, and wool pullers.⁸ Includes lime used by producers (captive tonnage) as follows—1943: 434,571 tons, valued at \$2,457,796; 1944: 432,166 tons, \$2,570,544.

PRODUCTION BY USES

The use pattern of lime shifts from year to year as circumstances change. During recent years the emphasis has been upon direct or indirect war uses. Agricultural, chemical, and industrial uses have attained much greater prominence than applications to the building trades.

Lime and other liming materials used in agriculture.—The total effective lime content of all agricultural liming materials sold in 1944 increased 29 percent over 1943. The principal gain as indicated in the following table was in agricultural limestone sales.

Building lime.—As there has been limited recent activity in the types of construction that employ lime as mortar or plaster, sales of building lime continued in 1944 the downward trend that has characterized the war years.

¹ Effective lime contents as follows: Quicklime, 85 percent; hydrated lime, 70 percent; limestone and oystershells, 47 percent; calcareous marl, 42 percent.

² Figures supplied by Fish and Wildlife Service.

³ Preliminary figure.

Chemical and industrial lime.—Although there was a decided drop in the quantity of lime used in ore dressing, the over-all use in metallurgy amounted to nearly 27 percent of total lime sales in 1944. Paper making, the second largest use, continued its decline as in 1943, but calcium carbide manufacture consumed increasingly large quantities. This was to be expected because of the wide use of acetylene gas in welding and in the active program of synthetic rubber manufacture. Neutralization of waste acids was included in 1944 in the item designated "Sewage and trade-wastes treatment." This no doubt accounts for the large increase for this use indicated in the accompanying table.

HYDRATED LIME

Production of hydrated lime, which gained slightly in 1944, represented 20 percent of the total output compared with 20 percent in 1943 and 21 percent in 1942. Active hydrating plants numbered 140 and were distributed in 34 States and 2 Territories. The following table shows production by States.

Uses.—The use of hydrated lime in building construction, metal-lurgy, insecticides, and water purification declined considerably. The most notable gains were in agriculture, food products, sewage treatment, and sugar manufacture. Although direct sales for insecticide use show a decline, considerable quantities sold for agricultural use probably were employed by farmers as insecticide.

TRENDS IN PRINCIPAL USES

Building-lime sales generally follow the trend of total new construction, but as indicated in figure 1, since 1939 their paths have

diverged widely. Total new construction made decisive gains, but building-lime sales dropped to low levels because war construction dominated all building activities. For the past 20 years, refractory lime (dead-burned dolomite) used for furnace linings and lime em-

FIGURE 1.—Sales of refractory and building lime compared with total new construction and industrial production, 1925-44. Units are reduced to percentages of the 1935-39 average. Statistics on value of construction from the Bureau of Foreign and Domestic Commerce and on industrial production from the Federal Reserve Board.

ployed in the chemical and manufacturing industries, as shown in figure 1, have followed very closely the volume of industrial production.

Trends in sales of "open-market" lime for its principal uses during the past 20 years are indicated in figure 2. Except for the moderate

FIGURE 2.—Trends in major uses of lime, 1925-44.

recession in 1938, chemical lime has shown a strong upward trend since 1932, although there was a slight decline in 1944. Building lime receded greatly during the depression, recovered moderately thereafter, but dropped precipitously during the war years. Refractory lime

(dead-burned dolomite) has followed a course closely paralleling that of chemical lime. Sales of agricultural lime have experienced only moderate fluctuations throughout the 20-year period.

SHIPMENTS

Total shipments.—Output exceeded apparent consumption in 13 of the 36 lime-producing States in 1944. The excess of out-of-State over into-State movements was large only in Missouri, Ohio, Tennessee, and West Virginia.

Sales, shipments, and supplies of lime available for consumption in continental United States, by States and groups of States, are listed in the two following tables:

Lime supplies available in continental United States in 1944, by States, in short tons

MILL VALUES

The net mill realization (excluding container cost) per ton of lime sold in the open market in 1944 averaged \$7.52, a gain of 8 cents over 1943 and 25 cents over 1942. The small gain in 1944 evidently reflects the upward revisions allowed by the Office of Price Administration in certain localities. The largest increase (55 cents) was in agricultural lime. Chemical and refractory lime increased 5 cents a ton, whereas building lime declined 7 cents.

NEW DEVELOPMENTS

Ordinary magnesium lime hydrates are generally incompletely hydrated. Recent tests at the National Bureau of Standards have demonstrated that when they are almost completely hydrated by

special treatment they possess superior qualities when used in masonry mortars.

Increasing interest is apparent in the recovery and re-use of lime used in water softening. The sludge contains not only lime carbonate derived from the original lime added to the water but additional carbonate precipitated from the water itself. The difficulty of sludge disposal has created a strong tendency toward developing methods of utilization. The material recovered may be used as a finely divided calcium carbonate for the whiting trade, or it may be recalcined and re-used in water treatment.

SIZE OF PLANTS

The trend that has been apparent during the war years toward inactivity of small lime plants continued in 1944. The large plants have evidently been able to weather the difficulties due to labor shortage and price restrictions better than the small plants. The output of all plants producing less than 25,000 tons was only 13 percent of total lime production in 1944; in 1943 it was 15 percent.

GENERAL SUMMARY

Some clays that have specialized industrial uses fared very well in 1944, whereas others that serve the construction field were at a very low ebb.

As the country lacked both the material components and manpower required for a large building program the brick industry operated at only a small fraction of its capacity. Some companies had difficulty in satisfying even the local demand, but usually this was due to suspension of output from competitive brick plants and to lack of manpower. The combination of low volume, increased costs, and frozen prices made profitable operation difficult and in some cases impossible.

Although fire clays felt the decline in construction of new furnaces, sales for furnace maintenance minimized the decrease in demand.

Bentonite took advantage of the expanded oil-well drilling program that required large quantities for drilling mud and again established a new production record.

Capacity output of petroleum products has rejuvenated fuller's earth, and by 1944 it had recovered nearly all the volume lost during the depression.

Ball clay and kaolin experienced good but not record sales.

In response to urgent requests from producers the Office of Price Administration authorized some minor price increases to offset costs that have risen during the war.

Some care should be exercised in comparing the clay statistics recorded in this chapter with those of previous years. Formerly the Bureau of Mines attempted to confine its statistics to "merchant clay," the tonnage that is marketed as raw or beneficiated clay. This practice presented a reasonably complete report for kaolin, ball clay, bentonite, and fuller's earth; but for fire clay and the "miscellaneous" clays it proved inadequate, as such a large proportion of the total

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

production of these types comes from mines operated by the companies that convert the clay into brick and other products before sale. During the past few years somewhat more complete information was provided by including all material that was mined at such a distance from the kilns that "shipment" of the raw clay was required before delivery to the plant. However, it is believed that a report showing the quantity of clay sold on the open market, the captive tonnage, and the total clay sold or used by producers will be of greater value, and that general principle is followed in this chapter. Comparability with former years is indicated at appropriate points in the following discussion of individual types.

Salient statistics of the clay industry in the United States, 1943-44

¹ Revised figure.

POSTWAR PROSPECTS

In 1944 the average operator of a structural-clay products plant would have expressed himself as discouraged with current conditions, but he anticipates a large market after the war. The need for new homes and other structures has been accumulating for years, and although serious financial problems remain to be solved it is generally felt that a major building program is coming. Virtually all postwar studies indicate that construction will be encouraged as a means of achieving the desired level of employment. Probably a fair share of the building dollar would come to the brick plant simply from habit, but progressive companies are improving their products, plants, and methods to enable them to hold their markets in the face of the strong competition that is expected from wood, glass, plastics, metal, and other structural materials.

As fire clay, bentonite, and fuller's earth are closely coupled to war production they are expected to decline somewhat, but as they also serve peacetime industry their prospects are linked to the success of the general reconversion program.

Competition of foreign clays will be felt by ball clay and kaolin when shipping is again freely available, but American clays have price advantages and qualities that should enable them to hold their own.

CONSUMPTION AND USES

The accompanying table showing the tonnages of domestic clays consumed in various uses continues a series begun in 1921. The quantities shown for kaolin, ball clay, fuller's earth, and bentonite are directly comparable with those published in Minerals Yearbook, 1943. On the other hand, the fireclay and miscellaneous clay figures are only partly comparable with 1943, as they now include all the clay in each class rather than being limited to the quantity shipped. The figures that are not comparable are indicated by footnotes.

¹ Revised figure.

CHINA CLAY OR KAOLIN

Although sales for some uses, such as rubber compounding, have declined, war conditions have not seriously interfered with kaolin production. During the 5-year period 1940-44 output of kaolin in the United States averaged 43 percent higher than in 1935-39. Since 1941 volume has been slowly receding—in 1944 it was 6 percent lower than in 1943.

Georgia furnished 77 percent of the tonnage and South Carolina 14; most of the remaining 9 percent came from North Carolina, Florida, and Pennsylvania.

Although in wartime the consumption of kaolin in paper is limited by the need for the stronger types of paper used in packaging, that industry, as usual, took the lion's share—59 percent of the total in 1944. Refractories consumed 12 percent, pottery 10, and rubber 7; the remaining 12 percent went into a variety of products, such as chemicals, paints, and plasters.

In harmony with the general decline in furnace construction, 30 percent less kaolin was used in refractories in 1944 than in the previous year.

The tonnage of rubber kaolin increased 17 percent, but only minor significance can be attributed to the rise. Synthetic rubber compounding requires large quantities of carbon black in preference to clay-type fillers, and in 1944 a serious shortage of carbon black encouraged the use of more clay than might otherwise have been considered desirable. The future size of the rubber-clay market remains to be determined by research in synthetics and policies governing postwar importation of natural rubber.

Demand for pottery kaolin has been very steady during the past 3 years.

Prices of kaolin changed little during 1944. Crude was quoted as low as \$2.50 per ton, and other grades ranged up to about \$40, depending upon location, degree of preparation, and special qualities. The bulk sells between \$6 and \$15 per ton. In 1944 producers reports showed a national average value of \$9 per ton. Trade journals quoted English china clay from \$19 to \$28 in lump form and \$40 to \$60 air-floated.

Imports of china clay declined 17 percent to 45,890 tons valued at \$487,237 in 1944. Twenty-six tons were reported as coming from Mexico and the remainder from the United Kingdom. Recognizing the equivalent quality of American kaolin, the Army and Navy Munitions Board removed English china clay from the list of strategic raw materials.

The high quality of American kaolin is so widely recognized that English producers are concerned over recapture of their American market. During the war labor and shipping limitations reduced the flow of English china clay to the United States. Although English clay will continue to find a market here, particularly in pottery, the opinion is widely held that its prospects of fully regaining its prewar tonnage are doubtful.

The State totals shown in the accompanying tables on kaolin are directly comparable with those published in Minerals Yearbook, 1943.

BALL CLAY

In 1944 sales of ball clay were 43 percent higher than the average for 1935-39. After setting a record of 198,445 tons in 1941, sales declined in 1942 and 1943, but in 1944 they increased 5 percent. Tennessee furnished slightly over 47 percent of the total and Kentucky slightly under 47 percent. The remaining 6 percent came from Maryland and New Jersey.

In addition to the sales tonnages recorded in the accompanying table, about 6,000 tons used by producers in making heavy clay products was reported as ball clay. Pending definite classification of this material it was tabulated with the miscellaneous clays. As no other captive tonnage was reported, only sales statistics appear in the ball clay table.

Imports of "common blue and ball clays" remained at only a little over half the prewar average—17,097 tons valued at \$157,631 came from the United Kingdom in 1944, and 500 tons valued at \$1,375 were credited to Canada. Consequently, imports satisfied only 10 percent of the ball-clay requirements of the United States in 1944.

Ninety percent of domestic ball-clay output was sold for use in pottery, 6 percent in high grade tile, and the remainder in a variety of uses, such as saggers and refractories. Demand in most uses has been rather erratic since 1941, but pottery requirements have been very stable.

Bulk, shredded ball clay was quoted in trade journals at \$3 to \$7 per ton and air-floated, in bags, from \$10 to \$18.25. The average value reported by producers to the Bureau of Mines in 1944 was \$8.84, slightly higher than the \$8.60 obtained in 1943.

FIRE CLAY

As the war has progressed, consumption of refractories in furnace maintenance has continued at a high level, but with the peak of new furnace construction past, output of fire clay declined 19 percent in 1944.

In recent years the tonnage of fire clay that was burned into clay products at the mine was mentioned only in the text, but this year it is included in the table showing total fire clay sold or used by producers. The relationship between the statistics contained in this and in former

reports is best-illustrated by the year 1943. As shown in the accompanying tables, sales were 2,477,593 tons, shipments for own use elsewhere were 2,223,551 tons, and the quantity burned into products at the mine or pit was 3,097,089 tons. The first two total 4,701,144 tons (the figure appearing as the United States total in Minerals Yearbook, 1943). The last two total 5,320,640 tons (the figure now recorded as "used by producer"). All three total 7,798,233 tons (the figure now recorded as the United States total).

Of the total fire-clay production in 1944 Ohio contributed 25 percent, Pennsylvania 22, Missouri 19, and the remaining 34 percent came from 27 other States. This ranking of Ohio and Missouri is the reverse of that cited in Minerals Yearbook, 1943, owing to the inclusion of the tonnage that is burned into clay products at the mine or pit. A substantial portion of this material is plastic fire clay that is used in making heavy clay products rather than refractories. In 1944 producers in Ohio reported 530,371 tons of fire clay used in heavy clay products, Pennsylvania 167,746, and Missouri only 10,659.

Fire clays have diverse physical and chemical properties that make them useful in the many products shown in the use table, but in 1944 refractories consumed 78 percent and heavy clay products 17.

The average value of fire clay sold on the open market was the same in 1944 as in 1943—\$2.48 per ton. The valuation of the captive tonnage is lower—\$2.08 in 1943 and \$2.12 in 1944—owing to its somewhat lower average quality and lower cost, which influences estimates of values attributed by producers.

Foreign shipments of fire clays have been well-maintained during the war. The United States Department of Commerce reported that exports totaled 87,737 tons valued at \$571,111 in 1944, whereas none was imported.

BENTONITE

In 1944 bentonite production increased 14 percent to over one-half million tons and for the sixth consecutive year established a new record.

Although consumption in nearly all uses was well-maintained, the principal expansion was in rotary drilling mud. Bentonite owes its growth in this market not only to the increase in the number of holes drilled but also to the greater average depth and to the relatively higher proportion of holes drilled with rotary rather than cable equipment. Consequently, whereas in 1944 about one-third more oil wells were drilled than in 1943, 76 percent more bentonite was consumed in drilling mud.

Wyoming and South Dakota were the principal beneficiaries of the expansion; decreases were reported in several States. Wyoming supplied 36 and South Dakota 31 percent of the total output.

As production capacity was ample to meet demand the War Production Board did not find allocation necessary. However, a shortage of railroad cars in the West seriously impeded deliveries from time to time, and the assistance of Government agencies was required to maintain a uniform flow of shipments.

Mine-run bentonite may be valued as low as \$2 a ton. Trade journals quoted dried and crushed, f. o. b. mines, at \$7.50; pulverized,

FIGURE 1.—Bentonite sold or used by domestic producers for specified uses, 1934—44.

200-mesh, \$9.50 to \$11; and 325-mesh, bagged, at \$16. Owing to the sale of a larger proportion of higher-priced grades the average value reported by producers increased from \$6.24 per ton in 1943 to \$6.60 in 1944.

The United States Department of Commerce reports that no bentonite was imported in 1944. Exports are not separately listed, but producers reported to the Bureau of Mines that they shipped 19,925 tons to Canada, Mexico, South America, Portugal, India, and Australia. This figure does not include some foreign shipments by dealers, nor does it include acid-treated bentonite exported for oil refining.

The State totals in the accompanying table are directly comparable with those published in previous years.

¹ Included under "Undistributed."² Figures include States indicated by "(1)."**FULLER'S EARTH**

The rapid recovery in the production of fuller's earth is continuing.

Owing to heavy competition from activated earths and synthetic substitutes fuller's earth lost ground steadily after 1930. By 1940 output had declined to 146,568 tons, but by 1944 it had risen to more than double that figure. Wartime demands for petroleum products, shortages of competitive materials, and new absorbent uses have all contributed to the recovery that has nearly reached record levels. Only in 1929 and 1930 has volume been greater. In 1944 output was 19 percent greater than in 1943.

Producers reported that 61 percent was consumed in mineral-oil refining, 8 percent for vegetable oils, and 31 percent for various applications such as in rotary drilling mud, in foundries, as an absorbent of grease on floors, and for other filtering and clarifying.

Although the Georgia-Florida district produced 44 percent of the total tonnage, Texas, with 38 percent, had the largest output of any individual State.

Only minor price increases were allowed by the Office of Price Administration in 1944. Trade journals quoted domestic fuller's earth from \$7 to \$15 per ton in bags, and imported from \$30 to \$40. These prices indicate the general range of valuation, although some special products exceed them, and some cruder materials are sold for less than \$7 per ton. The average value rose from \$10.77 in 1943 to \$11.19 in 1944. Material from Georgia-Florida was valued at \$14.25 per ton, from Illinois at \$9.23, and from Texas at \$8.24.

Only 308 tons of fuller's earth valued at \$4,284 were imported in 1944—all from the United Kingdom. Exports are not separately recorded by the United States Department of Commerce, but producers reported to the Bureau of Mines that they sent 7,459 tons valued at \$76,344 to Canada, the Persian Gulf, and South America, slightly more than the 6,842 tons reported for 1943.

FIGURE 2.—Mine shipments of fuller's earth compared with petroleum-refining activity (Federal Reserve Board Index), 1923-44.

As sales and consumption of fuller's earth by producers cannot be published without revealing the figures of individual companies only totals are shown in the accompanying table.

Fuller's earth sold or used by producers in the United States, 1942-44, by States

² Comprises following States: California, Colorado (1942), Nevada, Tennessee (1943-44), and Utah.

MISCELLANEOUS CLAYS

Clays vary so widely in their properties that it is usually very difficult to arrive at a generally accepted definition for each class. Kaolin, bentonite, and other types discussed separately in this chapter have widely, though by no means universally, recognized character-

istics. There remain a few clays of limited use, such as slip clay, and a great tonnage of other clays and shales used principally to make structural clay products. These are treated as a group in this section.

As most of this material is used in making heavy clay products and cement its value is low. A few specialties like slip clay and drilling mud range up to and over \$10 per ton, but the bulk is worth less than \$1 per ton. As comparatively little is sold as raw clay its valuation is largely an attributed market value estimated from known production costs.

For the reasons outlined at the beginning of this chapter the statistics in the accompanying table cover all miscellaneous clay output reported to the Bureau of Mines rather than only the portion that is shipped before use.

Owing to a substantial decline in cement manufacture and a moderate reduction in shipments of clay products, output of miscellaneous clays in 1944 was 19 percent lower than in 1943.

¹ Includes following—1943: slip clay from Michigan and New York, 5,386 tons \$47,386; 1944: 2,831 tons, \$25,322. Purchases of common clay and shale by cement companies—1943: 381,360 tons, \$190,678; 1944: 259,218 tons, \$129,006.

² Comprises following: Shipments for own use elsewhere—1943, 353,794 tons, \$274,343; 1944, 293,271 tons, \$294,948. Common clay and shale burned into clay products at mine or pit—1943: 6,562,991 tons, \$4,265,944 (estimated); 1944: 5,621,809 tons, \$3,649,724 (estimated). Common clay and shale used by producer in cement manufacture—1943: 3,622,956 tons, \$1,811,476 (estimated); 1944: 2,563,663 tons, \$1,281,830 (estimated).

³ Included under "Undistributed."

⁴ Figures include States indicated by "(³)" and Arizona (1943 only), Delaware, District of Columbia, Florida, Idaho, Maine, Minnesota, New Hampshire (1943 only), New Mexico, North Dakota, Puerto Rico, and Vermont.

CLAY PRODUCTS

The structural clay products industry was depressed in 1944. War construction and private building furnished a meager demand. As in 1943, low volume and high labor and material costs plagued operators, and nearly half of them had either shut down completely or were shipping from inventory. Many said that their output was limited by labor shortages and price problems. In several areas the Office of Price Administration permitted modest price increases.

On the other hand, anticipation of a postwar building boom lightened the atmosphere, and producers were urged to modernize their plants and methods and prepare themselves for future high production.

During the war, production of art pottery has increased owing to interruption of imports, and shortages of competitive articles.

The accompanying chart, drawn from information furnished by the War Production Board, shows the contraction in output and inventories of unglazed brick during the war.

FIGURE 3.—Production, shipments, and inventories of unglazed brick, 1941-44.

TECHNOLOGIC DEVELOPMENTS

To prepare their companies to meet future opportunities and competition, progressive operators are improving their plants and products. Better heat insulation, easier placement, acoustical insulation, modern appearance, and even radiant heating are some of the advantages claimed for various structural shapes. A step toward relatively lower building costs is the modular design that is strongly advocated by trade and technical associations. In the modular system, design is based on a 4-inch module or increment which enables the producer to offer shapes that will fit at the building site without wasteful cutting and fitting, an objective believed to be of particular value in brick and tile construction.

As tunnel kilns are not always more economical than periodic kilns many companies hesitate to install them. For such organizations, installation of highly mechanized small tunnel units was suggested as a means of gradually converting without disturbing production.² Thus over a period of time there would be accumulated a battery of small units that could be operated near capacity without losing flexibility to the market demands for a variety of products. Tunnel kilns are strongly advocated because they lend themselves to mechanization which reduces labor costs and breakage. It has been predicted that over 100 tunnel kilns will be installed after the war.³

³ Brick and Clay Record, Can You Afford Not To Install Tunnel Kilns: Vol. 104, No. 5, May 1944, pp. 17-20.

As a war measure, sponge iron is being produced in brick kilns. Alternate layers of iron ore and anthracite are put in saggars (flue tile) and burned at ordinary brick temperatures.⁴

A description of a method for rapid identification of clays, by differential thermal analysis, was published in 1944.⁵

Closer coordination between producers and consumers of refractories is enabling better refractories to be developed as they can be tested for performance under service conditions during development. With a clear picture of the commercial specifications that must be met, producers can set up adequate inspection and control systems. On the other hand, complete testing in service is too slow for an aggressive development program so there is a constant urge for new and more rapid tests. The Panel Spalling test revealed the virtues of superduty brick. X-ray and microscopic analyses now often displace the slower chemical analysis.⁶

A description of the effects of addition of clay and shale to mortar was published in 1944.⁷

Although naval attacks on our bauxite supply lines had been successfully repulsed by 1944, hope was retained that clay would prove its value as an ore of aluminum. Construction continued on the two plants that propose to produce alumina from clay. By the year end the lime-sinter-process plant of the Ancor Corp. at Harleyville, S. C., had started experimental production, and construction of the ammonium sulfate process plant of the Columbia Metals Corp. at Salem, Oreg., was well advanced.

GENERAL CONDITIONS

The output of the abrasives industries in 1944 totaled 1,340,909 short tons valued at \$34,403,056 and was only slightly under that of the industrially active year 1943. Domestic production of natural abrasives in 1944 amounted to 954,505 short tons valued at \$9,575,038, or 71 and 28 percent of the total tonnage and value, respectively, of all abrasives for which data are included in this chapter. The output of artificial abrasives in 1944 continued at a high level and was only 6 percent below that in 1943, the record year for these products. Ground sand and sandstone and metallic abrasives rose to new highs. Average annual sales of diatomite for the 3-year period 1942-44 were substantially higher than for similar periods heretofore reported. Marketed production of emery, pumice and pumicite, and tripoli were larger than in 1943. Domestic production of most of the other natural abrasive products herein discussed was somewhat less in 1944 than in 1943.

The total value of imports of natural abrasives in 1944 rose to \$23,456,221, or 4 percent greater than in 1943. Imports of bort (glazier's and engraver's diamonds, unset and miner's) again broke all records, and the continued tendency to use smaller industrial stones also was reflected in the decline in average value per carat to \$1.79. In 1944 this classification comprised about 96 percent of the total value of imported materials. Corundum imports were the highest on record, although receipt of diamond dust in 1944 dropped to less than half that reported for 1943. Imports of pumice, garnet, and tripoli in 1944 were very small. The total value of exports of abrasives and abrasive products in 1944 decreased 41 percent compared with 1943, owing chiefly to the sharply reduced export value of emery and corundum abrasive wheels.

This chapter includes data for most of the materials used chiefly as abrasives, although certain clays, oxides, and substances mentioned later under Miscellaneous Mineral Abrasive Materials are not included in the statistics presented herein. On the other hand, certain of the abrasive materials for which figures are shown also have important nonabrasive uses.

¹ Average annual figure for 1942-44. Accumulated total production for 3-year period 1942-44 was 524,877 tons, \$9,894,534.

² Data included in total; Bureau of Mines not at liberty to publish figures.

³ Data for oilstones and related products and corundum not included in totals; Bureau of Mines not at liberty to publish figures.

⁴ Tonnage of millstones not recorded.

⁵ Includes Canadian production.

⁶ Weight cannot be reported because of varying units.

POSTWAR PROSPECTS

The abrasives industry follows to a large extent fluctuations of the automobile and the so-called heavy industries. The military and naval armament and accessory equipment all require cutting, grinding, and smoothing or polishing and thus need abrasives either as loose grain, or in bonded or coated products of many different types. The contract obligations of most of the industries supplying these articles of war have not decreased materially with cessation of the war in Europe. Although perhaps a sizable demand will continue, eventually the greater part of this market will cease. Reconversion to civilian economy and to manufacture of durable goods for civilian consumption should result in a demand for abrasives. The increased

production of automobiles and the pent-up need for new railroad and industrial equipment also should contribute to a healthy demand for abrasive products in the postwar era.

The expected activity in construction of private and public buildings will be accompanied by the greater use of insulating materials. This will tend to stimulate nonabrasive outlets of diatomite and to a less extent of pumice. The wider acceptance of lightweight aggregates and lightweight concrete in construction also may increase diatomite and pumice sales.

Predicted new uses and new methods of tooling will produce far-reaching changes in the efficiency and the technique of processing diamonds and the ease and speed of operation.

NATURAL SILICA ABRASIVES

Diatomite.—The Bureau of Mines has not been at liberty to publish annual production statistics since 1926. Total output (sales) for 3-year periods, however, may be shown. Total sales for the three most recent such periods were as follows: 1942–44, 524,872 short tons valued at \$9,894,534; 1939–41, 360,502 tons valued at \$5,746,216; and 1936–38, 279,645 tons valued at \$4,377,353. The totals for the 1942–44 period are the highest yet reached and indicate record outputs in recent years for this product.

The principal producing States in 1944 as for many years, were California and Oregon. No sales were reported in 1944 for Florida or New Mexico. Other production came from the same additional States as in 1943—Idaho, Nevada, New York, and Washington.

Statistics of uses cannot be shown. It is possible, however, to indicate certain relationships and in general to report certain changes in trends of shipments. The principal uses for diatomite are for filtration, insulation, and fillers, with small tonnages for fine abrasives such as silver polish. Filtration, which generally consumes slightly over half the total output, rose to nearly 60 percent. Amounts used as fillers also increased, totaling about one-fifth of total sales. Other or miscellaneous uses were higher than in 1943. The figures reported for insulation in 1944, however, were somewhat less than in 1943, probably in large part because of the smaller output of refractories and steel in 1944 and the continued inactivity of the construction industries.

Quotations on diatomite in 1944 remained at the same levels as in 1943 and were reported in E&MJ Metal and Mineral Markets as follows (prices are per ton on a f. o. b. mill, Nevada, basis): Crude, in bulk, dried, \$7, nominal; 98- to 100-mesh, \$20; low-temperature insulation, \$19; high-temperature insulation, \$30; fine abrasive, 2 cents per pound. (Bags extra.) In February 1945 these quotations were changed as follows: Crude, in bulk, dried, \$10 per ton; 98- to 100-mesh, \$25; low-temperature insulation, \$25; high-temperature insulation, \$40; fine abrasive, 2 to 3 cents per pound. (Bags extra.) In March 1945 a quotation on filtration grades of diatomite in California was added: \$20 to \$50 per ton, f. o. b. mill.

The unusual properties of diatomaceous earth as a filter-aid have resulted in its extensive employment in pressure filters especially where the impurities are viscous or colloidal in character, as in the

filtration of oils, sugar, syrups, or cereal beverages.¹ A vitally important application of the filter-aid properties of diatomite is the development of portable high-rate pressure-type filtration equipment for the use of the armed forces in the field.²

Chesters,³ in a discussion of minerals and other substances used in steel-plant insulation, described the characteristics and properties of diatomite as an insulating medium in this field, both as natural sawed shapes and in the form of bricks of raw or calcined material. The preparation and use of diatomite (and other products) in high-temperature heat insulation and the application of heat-resistant materials to various types of ferrous and nonferrous foundries and to open-hearth furnaces were studied by Paterson.⁴

Ammonium nitrate, which is one of the cheapest known fertilizer materials, is extremely hygroscopic and tends to cake in storage. To counteract these unfavorable characteristics, granulation and coating of the resultant granules with a wax, followed by dusting with an inert mineral powder, are resorted to.⁵ A number of dusting agents have been used, including kaolin, limestone, diatomaceous earth, plaster of paris, and tricalcium phosphate. Extensive tests by the United States Department of Agriculture⁶ have indicated that diatomaceous earth is one of the most satisfactory conditioning materials available. Its use, it is claimed, promotes a free-flowing product and makes possible easy handling and spreading in the field, whether by hand or in standard drilling equipment. Also it tends to prevent caking, even after long periods of storage. Commercial use of diatomite as a dusting agent apparently is more prevalent in Canada than in the United States and has been reported by at least three Canadian firms manufacturing chemicals and fertilizers.

Tripoli.—Output of tripoli in 1944 increased 24 percent in both quantity and value compared with 1943, although considerably under other recent years. Production in Illinois, the only State for which data may be shown, was 18 percent higher than in 1943. Other States that produced in 1944 were Arkansas, Missouri, Oklahoma, and Pennsylvania (rottenstone).

The principal uses of tripoli are as abrasives—chiefly as constituents of polishing and buffing compounds—and as fillers. Tonnages reported sold for use as abrasives more than doubled in 1944 compared with 1943, and the quantity reported sold for fillers was about half the 1943 total. Concrete admixtures, foundry facing, and oil-well drilling mud were among the other uses specified.

² 1942 and 1944: Foundry facing, drilling mud, and unspecified; 1943: Filter block, foundry facing and unspecified.

As reported by E&MJ Metal and Mineral Markets, quotations on tripoli during 1944 remained at the same level as in other recent years (prices are per short ton, f. o. b. Missouri, in paper-lined burlap bags, minimum carlot 30 tons): Once-ground, through 40-mesh, rose- or cream-colored, \$14.50; double-ground, through 110-mesh, rose or cream, \$16; air-floated, through 200-mesh, \$26. Quotations on rottenstone, as given in Oil, Paint and Drug Reporter, were unchanged throughout 1944, as follows (prices are at mines, in bags): Carlots, \$25.50 per short ton; and less than carlots, \$37.50 per ton.

Firms actively producing tripoli in 1944 were: Arkansas—Corona Products, Inc., Rogers; Illinois (amorphous silica)—Olive Branch Minerals Co., Cairo, and Ozark Minerals Co., Cairo; Missouri and Oklahoma—Barnsdell Tripoli Corp., Seneca, Mo.; Missouri—Independent Gravel Co., Joplin; and Pennsylvania (rottenstone)—Penn Paint & Filler Co., Antes Fort, and Keystone Filler & Mfg. Co., Muncy.

Quartz.—Sales of crude, crushed, and ground quartz from pegmatite veins or dikes and from quartzite in 1944 were 17 percent less than in 1943 in both quantity and value. The total crude quartz sold in 1944 rose nearly 150 percent compared with 1943. A large drop in output of crushed quartz and a sizable decrease in reported sales of ground material were the chief factors in the over-all decline. Total sales in 1944, however, were higher than in any recent year other than 1943, although the average value per ton in 1943 and 1944 remained the same (\$3.48).

Quartz (crude, crushed, and ground)¹ sold or used by producers in the United States, 1940-44

Year	Crude		Crushed		Ground		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1940.....	3,606	\$17,099	17,652	\$58,897	10,807	\$100,394	31,865	\$176,390

1944.....	15,222	35,279	61,823	170,325	5,334	80,874	82,379	286,478

¹ To avoid duplication, the ground material shown here is only that ground by the original producers of the crude quartz or by grinders who purchase from small miners not reporting their production.

Eleven States reported sales of quartz in 1944, the same number as in 1943. The greater part of the output came from Western States and can be accounted for largely by the expanded ferrosilicon program in the Pacific Coast area. No production in 1944 was listed from Massachusetts, Ohio, Pennsylvania, or Texas.

Quotations on ground "hard quartz" silica, as reported by Oil, Paint and Drug Reporter at the beginning of 1944, were as follows: 325-mesh (99½-percent grade), carlots in bags, \$13.50 per ton, and less than carlots, \$18.50; 140-mesh (99½-percent grade), carlots in bags, \$11 per ton, and less than carlots \$16. These quotations remained unchanged throughout 1944, and the early months of 1945, except that carlots of 325-mesh material rose to \$15.50 in March 1944.

Ground sand and sandstone.—Sales of ground sand and sandstone in 1944 rose 3 percent in quantity and 1 percent in value compared with 1943 and totaled 558,606 short tons valued at \$3,989,981, a new high in both tonnage and value. Production each year since 1938 has been larger than in the preceding year. Output by States or groups of States, for which comparable data are presented, for the

most part indicated small decreases in 1944 compared with 1943, although production for Ohio, Virginia, and West Virginia combined was slightly larger than in 1943. Outputs for California-Washington and for "Other States" in 1944 also increased compared with 1943 data. States producing sizable tonnages of ground sand and sandstone are Illinois, New Jersey, Ohio, and Pennsylvania.

Distribution of sales of ground sand and sandstone by uses, as reported by firms producing 91 percent of the total sales, indicates that the principal customers for these products are the manufacturers of pottery, porcelain, and tile, foundry operators, and users of abrasives, particularly cleaning and scouring compounds, in order of size of shipments. Manufacture of glass and enamel and consumers of various types of fillers account for most of the remaining tonnage for which uses are reported.

¹ Data represent 91 percent of the industry.

Abrasive sands.—Natural sands with a high silica content are employed for sand blasting, stone polishing, glass grinding, coating sandpaper, or other abrasive purposes. Total sales of such grinding and polishing sand in 1944 amounted to 897,983 short tons valued at \$1,563,511, compared with 837,662 tons valued at \$1,428,463 in 1943—an increase of 7 percent in tonnage and 9 percent in value. In 1944 these data included 482,293 tons of blast sand valued at \$1,228,744 and in 1943, 450,997 tons valued at \$1,138,003.

SPECIAL SILICA-STONE PRODUCTS

Grindstones and pulpstones.—Production of grindstones in 1944 decreased 13 percent in quantity and 9 percent in value compared with 1943 and was the lowest output since 1940. Sales of pulpstones also were less in 1944 than in 1943. Actual data, however, may not be published. As in most recent years, grindstones were produced in Ohio and West Virginia. Output of pulpstones was reported only from West Virginia.

¹ Bureau of Mines not at liberty to publish figures.

Oilstones and related products.—Sales of natural sharpening stones, including oilstones, whetstones, scythestones and rubbing stones, were slightly higher in 1944 than in 1943. The Bureau of Mines, however, has not been at liberty to publish sales figures since 1939. States that produced in 1944 and the type of stone reported from each State were as follows: Arkansas—oilstones and whetstones; Indiana—rubbing stones; New Hampshire—scythestones; and Ohio—scythestones, whetstones, and “other” sharpening stones, including lathestones.

Millstones.—The value of sales of millstones in 1944 increased 5 percent, to \$9,700, compared with \$9,240 in 1943. Output, as in 1943, was reported from Ulster County, N. Y., Rowan County, N. C., and Montgomery County, Va.

Grinding pebbles were produced in six States in 1944—California, Minnesota, North Carolina, Texas, Washington, and Wisconsin, and tube-mill liners were reported from three States—Minnesota, North Carolina, and Wisconsin.

John T. Momand, Carlsbad, Calif., reported sales of beach pebbles in 1944. Quartzite liners and artificially rounded quartzite grinding pebbles were prepared by Jasper Stone Co., Sioux City, Iowa, from quarries at Jasper, Minn. Southern Products & Silica Co., Lilesville, N. C., produces Texas flint pebbles at its plant at Glidden, Tex., and mills and markets silica (quartz) pebbles from deposits at Lilesville, N. C. Some of the crude Texas pebbles also are processed at Lilesville. Harris Granite Quarries Co., Salisbury, N. C., and Peeler & McCombs, Faith, N. C., both sold rounded granite cubes and granite liners in 1944. Dezendorf Marble Co., Austin, Tex., shipped some flint pebbles, and Mineral Products Co., Seattle, Wash., sold grinding pebbles from Stevens County, Wash. Quartzite pebbles and liners also were marketed by Baraboo Quartzite Co., Baraboo, Wis.

The search for grinding pebbles in this country after cessation of European imports at the outbreak of World War II led to the development of the Texas flint-pebble deposits. The part played in this search by the Southern Products & Silica Co. was briefly reviewed, and the flint-pebble operations at this company's mills at Glidden, Tex., and Lilesville, N. C., were described by Trauffer.⁷ In connection with the possibility of foreign competition now that the European phase of the war is over, it is understood from correspondence received by the senior author that importation of French and Danish pebbles cannot be expected in substantial quantity for some time, as the coastal areas in the regions of the pebble deposits were heavily mined and must be cleared before the pebbles can be gathered.

NATURAL SILICATE ABRASIVES

Pumice and pumicite.—Output of pumice and pumicite in 1944 increased 4 percent in tonnage and 15 percent in value compared with

⁷ Trauffer, W. E., Grinding Pebbles from Texas Help to Supply Demand as Imports Cease: Pit and Quarry, vol. 37, No. 3, September 1944, pp. 80-81.

1943, although it was still considerably under the high levels of 1941 and 1942. However, sales in 1944 were larger than in any year previous to 1941.

Production was reported in seven States in 1944, the same number as in 1943—output was listed from Oregon in 1944 and none was reported from Oklahoma. The principal producing States, as in 1943, were Kansas and California. The value of production in Kansas in 1944 did not change materially, although that in California rose 23 percent in quantity and 53 percent in value.

Abrasive manufacture remained the largest use of pumice and pumicite in 1944 and accounted for about 72 percent of total sales. (See fig. 1.) Cleansing and scouring compounds and hand soaps showed a small decrease in tonnage and a slight increase in value. Pumice and pumicite sold for other abrasive use increased in both quantity and value. Although private construction activity continued at a comparatively low level, sales of pumice and pumicite for use in concrete admixture and concrete aggregate in 1944 were somewhat above 1943 figures and were responsible almost entirely for the increased quantity of total sales of these products in 1944. Sales for acoustic plaster again decreased sharply compared with the previous year. "Other uses" gained slightly in tonnage in 1944 compared with 1943 and included, in 1944, sales for use in insecticides, insulation, brick manufacture, filtration, and solvents.

Experiments using pumice as a flux in the smelting of iron sand were reported from New Zealand.⁸ Corrosion of the clay crucibles used was considerable. Quotations on pumice as reported by E&MJ Metal & Mineral Markets during 1944 and the early part of 1945 were as follows: F. o. b. New York or Chicago, in barrels, powdered—2¼ @ 4½ cents per lb., and lump—5@7½ cents per lb.

Garnet.—Sales of abrasive garnet in 1944 were somewhat less than in 1943, although the Bureau of Mines is not at liberty to publish production data. The trend of garnet production before 1944 is shown in figure 2. Output of garnet in 1944 was reported from Idaho and New York. Two companies were active near Fernwood, Idaho—Spokane Garnet Sand & Sales Co., and Garnet Mines, Inc., both with offices in Spokane, Wash. Barton Mines Corp., North Creek, was producing in New York. According to the trade press, the latter firm has recently installed equipment to prepare superfine garnet flour which has been used to supplement shortages of corundum superfines in the precision grinding of optical glass.⁹

Quotations on domestic garnet in 1944 as reported by E&MJ Metal & Mineral Markets were unchanged from previous listings: New York Adirondack garnet concentrates, grain—\$85 per short ton. Quotations on Spanish garnet were discontinued.

⁹ Pit and Quarry, vol. 37, No. 10, April 1945, p. 59.

¹ Bureau of Mines not at liberty to publish figures.

Grinding to -35-mesh (25 percent minus 200-mesh), desliming, and flotation in the presence of a fatty acid and a small amount of sulfuric acid effected a satisfactory recovery of garnet (and kyanite) on an ore containing 8 percent garnet, 13 percent kyanite, 30 percent mica, and 45 percent quartz and feldspar plus minor amounts of other constituents.¹⁰ A recent patent for a new synthetic abrasive product described the sintering of garnet and aluminum oxide at a temperature of 1,500° C. or higher, causing a fusion of the garnet and agglomeration of the Al_2O_3 fines.¹¹ The resultant abrasive granules after cooling, grinding, and sizing are said to have a hardness of 8 or greater (Mohs' scale) and can be bonded by the commonly used bonding materials.

NATURAL ALUMINA ABRASIVES

Corundum.—Corundum, a natural alumina abrasive, Al_2O_3 , has been especially in demand for use in the manufacture of grinding or snagging wheels essential to heavy industry (particularly to those firms manufacturing heavy equipment for the armed forces) and also is employed as an important polishing agent for vitally necessary precision lenses. The coarser grain sizes are purchased by the snagging-wheel manufacturers and the finer-sized products by optical-lens makers. The fine dust, with its admixed minute particles of glass, is

¹⁰ Falconer, S. A., and Crawford, B. D., Froth Flotation of Some Nonsulphide Minerals of Strategic Importance: Am. Inst. Min. and Met. Eng. Tech. Pub. 1754, 1944. 16 pp.

¹¹ Brown, John A. (assigned to Minnesota Mining & Manufacturing Co.), Abrasive Material: U. S. Patent 2,358,313, Sept. 19, 1944; Chem. Abs., vol. 39, No. 7, Apr. 10, 1945, p. 1522.

sold to retail opticians, both in this country and in many parts of the world.

Until 1943 no production of natural corundum had been reported in the United States since 1917 and 1918 and none previous to those years since 1906. Although a small output of corundum was made in 1943 and 1944 for test purposes, this project has now been discontinued. Activity in North Carolina and Montana at the end of 1944 had not progressed beyond experimental stages.

Most of the corundum used in this country for many years has been obtained from the Union of South Africa, which in most normal years has maintained a fairly steady supply, despite distance of market and transportation difficulties. In the last year or so, however, production has not kept pace with demand, and efforts in the Union and plans of the Foreign Economic Administration to secure wider and better exploitation have not achieved the desired results. The opening of new deposits and improved mining and concentrating methods would be of great benefit to this South African industry.¹² Shipments from the Union of South Africa in 1943, which were smaller than in 1942, continued at approximately the same rate through the first half of 1944, at least, yet were considered insufficient to meet the strong demand, particularly from the United States.¹³ Supplementing the corundum from the Union of South Africa, shipments of small quantities from other countries have occasionally been received, including material recovered from old tailings dumps.

A general discussion of corundum appeared late in 1944.¹⁴

Prices on crude corundum imported into the United States do not appear in domestic trade journals. However, quotations on prepared sizes of natural corundum, as given in E&MJ Metal & Mineral Markets, beginning in March 1944, were as follows: Per pound, sizes 8 to 60, incl., 8½ cents; 70 to 275, incl., 9½ cents; 500, 30 cents; 850, 45 cents; 1,000, 45 cents; 1,200 to 1,600, 65 cents; and 2,600, 70 cents.

Ceramic materials as substitutes for tool steel in gages present interesting postwar possibilities. Plug gages of 85 or 90 percent corundum-base composition have gaged 350,000 steel cartridge cases with the same degree of wear as tool-steel gages after only 15,000 cases.¹⁵ Other types of ceramic gages also were described. Laboratory flotation tests on a 3-percent corundum ore were described by Falconer and Crawford.¹⁶ In order to achieve best results it was necessary to thoroughly deslime the flotation feed. A 54-percent concentrate and an additional 8 percent in tailings were obtained with a high percentage recovery of corundum. Flotation was rapid, and the consumption of reagents was not excessive.

Emery.—Sales of domestic emery in 1944 increased 4 percent in quantity and 3 percent in value compared with 1943 (see fig. 2) and reached 6,940 short tons valued at \$64,858—the highest figure since 1918. The entire output, as in former years, was mined in the Peekskill, N. Y., region. The chief uses of emery are in abrasive products,

NATURAL CARBON ABRASIVES¹⁷

Industrial diamonds are produced largely in the Belgian Congo, and a large proportion of the rest of the world production comes from Gold Coast, Sierra Leone, and Angola. Record sales of industrials in 1943 totaled about £6,000,000. Sales have exceeded output in recent years, the value of 1943 sales being over twice that of present production. Since stocks are low and skilled sorters are few due to the war, 1944 sales, although undoubtedly at a high level, were expected to be somewhat smaller than in 1943. The exceptionally active market reflects the dependence of industrial production, civilian and military—with its closer tolerances, large-scale methods and tougher, harder alloys—upon the abrasive (and abrasion-resistant) qualities of the diamond. To provide a reserve for emergency use outside the Union of South Africa, a substantial quantity of industrial grades has been transferred to Canada,¹⁸ where they may be drawn upon, when needed, both by that country (Canada) and the United States, whose industries consume by far the greater share of the world sales.

An excellent summary of all phases of the diamond industry—production, marketing, consumption, industrial and gem—appeared in 1944.¹⁹ A comparison of the abrasive properties of the diamond with other natural and manufactured abrasive materials included, in tabular form, structural and physical properties of many of the more commonly used abrasives.²⁰ The establishment of a large diamond-cutting industry for fine-size diamonds in the United States following invasion of the Low Countries, the revolutionary application of machinery and assembly-line methods to cutting operations, and the probable development of new uses for diamonds in postwar industry were discussed by Walker.²¹ Uses and description of diamonds, and the applications in industry of diamond dust and drilling, shaped,

natural, and die stones were presented by Rockwell.²² Detailed descriptions of diamond deposits in Bolivia,²³ Gold Coast,²⁴ South-West Africa,²⁵ northeastern Angola,²⁶ and the Ural Mountains in U. S. S. R.²⁷ were published.

ARTIFICIAL ABRASIVES

Total production of artificial abrasives in 1944 aggregated 386,404 short tons, valued at \$24,828,018, or 6 percent less in tonnage and 5 percent less in value than in 1943. The combined total, however, of these manufactured abrasive products—silicon carbide, aluminum oxide, and metallic abrasives (steel shot and grit)—was larger than in any year except 1943. Production of silicon carbide in 1944 decreased 19 percent in quantity and 20 percent in value compared with 1943, this decline approximating the drop in used capacity—98 percent in 1943 and 78 percent in 1944. The output of aluminum oxide in 1944 was 15 percent under 1943 and similarly reflected operation considerably under capacity—79 percent in 1944 compared with 98 percent in 1943. Shipments of metallic abrasives (steel shot and grit) rose in 1944 to a new record in both quantity and value—144,540 short tons valued at \$8,441,505, or 16 percent higher in tonnage and 19 percent higher in value than in the previous peak year (1943). Operation was at 75 percent of capacity.

A compilation of data on stocks and capacity, as reported by the producers, shows variations in inventories and capacity over a period of years.

Crude artificial abrasives sold, shipped, or used, from manufacturing plants in the United States and Canada, 1940-44

¹ Production; Bureau of Mines not at liberty to publish data for United States separately. Figures include material used for refractories and other nonabrasive purposes.

² Figures include only shipments from United States plants.

Production of silicon carbide and aluminum oxide largely is concentrated in the Niagara Falls region of Canada and the United States; some aluminum oxide, however, is produced in Quebec, Canada, and in Alabama. The same companies that produced aluminum oxide and silicon carbide in 1943 and other recent years were active in 1944. The total for aluminum oxide in 1944 included 25,868 short tons of "white high-purity or special" material, valued

at \$2,847,167—a decrease of 8 percent in quantity and 11 percent in value compared with 1943. Silicon carbide consumed in refractory or nonabrasive uses in 1944 was estimated at 43 percent of total production compared with 41 percent in 1943 and 35 percent in 1942. Similar data for aluminum oxide indicate only a small percentage of total output employed for nonabrasive or refractory purposes—3 percent in 1944, 4 percent in 1944 and 3 percent in 1942.

Stocks and capacity, as reported by producers of artificial abrasives, 1935-44, in short tons

¹ Data not available.

Statistics for metallic abrasives cover steel shot and grit (including figures for one firm that manufactures a similar product from salvaged wire clippings) but not steel wool. In 1944, metallic abrasives were manufactured in Massachusetts, Michigan, New Hampshire, New York, Ohio, and Pennsylvania. The principal producing States, in order of production, were Ohio, Michigan, and Pennsylvania. Thirteen companies with 14 plants reported shipments in 1944, compared with 12 companies and 13 plants in 1943. A new plant in the Chicago area was beginning regular production early in 1945, and another firm was said to be planning erection of a plant in 1945 to manufacture abrasives in the same general region.

Producers of metallic abrasives in 1944 were the following:

Western Metal Abrasive Co., 2545 East 79th St., Cleveland 4, Ohio—plant at Chicago Heights, Ill. (production in 1945).

Holden & Norris, Inc., Wilmington, Mass.

Industrial Metal Abrasives Co., 1603 Wildwood Ave., Jackson, Mich.

Cleveland Metal Abrasive Co., 887 East 67th St., Cleveland 8, Ohio—plant at Howell, Mich.

Clayton-Sherman Abrasive Co., 3896 Lanyo Road, Detroit 10, Mich.

Harrison Abrasive Corp., 887 Chestnut St., Manchester, N. H.

Abrasive Shot & Grit Co., 1 Carolina St., Springville, N. Y.

American Steel Abrasives Co., Sherman, East and Charles Sts., Galion, Ohio.

Cleveland Metal Abrasive Co., 887 East 67th St., Cleveland 8, Ohio—plant at Cleveland.

National Metal Abrasive Co., 3560 Norton Road, Cleveland 11, Ohio.

Steelblast Abrasives Co., 6536-40 Carnegie Ave., Cleveland, Ohio.

Cut Steel Abrasives, Inc., 1609 Wilson Ave., Youngstown, Ohio.

Globe Steel Abrasive Co., 238 First Ave., Mansfield, Ohio.

Pittsburgh Crushed Steel Co., 4839 Harrison St., Pittsburgh, Pa.

Philadelphia Steel Abrasive Co., Vandalia and McKean Sts., Philadelphia 48, Pa.

Electrochemical and similar industries in the Niagara Falls region were described and their products enumerated in a 1944 release.²⁸ An account of the historical development and growth of the Exolon Co., Tonawanda, N. Y., one of the manufacturers of silicon carbide and fused aluminum oxide appeared early in 1945.²⁹ Properties and uses of silicon carbide were discussed.³⁰ Russian tests recently reported in Ceramic Abstracts³¹ indicate that the efficiency of boron carbide may be 40 to 70 percent of that of diamond dust.

Bombarding metal surfaces with steel shot not only improves surface finish, thereby reducing need for further polishing, but makes such surfaces distinctly more resistant to destructive corrosion and actually increases fatigue strength.³² More effective with thin work pieces, this so-called "shot peening" is applicable to irregular shapes or to specific areas and reduces costs materially.

MISCELLANEOUS MINERAL ABRASIVE MATERIALS

In addition to the natural and manufactured abrasive materials discussed herein, many other mineral substances are used for abrasive purposes. Various oxides, including tin oxide, rouge, crocus, chromium oxide, magnesium oxide and manganese oxide, are utilized as polishing agents. Preparation of cerium oxide as an abrasive in polishing glass has been developed recently in Canadian plants and adopted by many United States firms. Ceria is more efficient and cleaner in action and effects a saving of 30 to 60 percent in polishing time, which more than offsets its higher cost.³³ Among manufactured or artificially prepared products used or intended for use as abrasives may be mentioned boron carbide and a periclase abrasive made from magnesite. Finely ground or calcined clays, high-grade lime, talc, feldspar, river silt, slate flour, whiting, and other substances also have specialized abrasive applications.

FOREIGN TRADE³⁴

The total value of imports of abrasive materials in 1944 increased about 4 percent over 1943. This increase was due almost entirely to a 4-percent rise in imports of bort (glaziers' and engravers' diamonds, unset, and miners'), this classification comprising largely what are known as industrial diamonds. Reflecting the actively supported demand for corundum, imports of corundum ore in 1944 increased 13 percent in tonnage and 31 percent in value compared with 1943, and were the highest at least since 1924. (Before that year, corundum and emery ore were combined in one import classification, and data were not available separately.) No imports of emery ore were reported for 1944. Other classifications of emery and corundum and of diamonds generally decreased compared with 1943. "Flint, flints, and

³⁴ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

flint stones, unground," which includes grinding pebbles, increased 35 percent in tonnage but still was much less than in prewar years. No prepared or "manufactured" pumice was imported in 1944. Receipts of garnet, tripoli, and crude pumice were very small.

The average value (foreign market value) of corundum in 1944 again rose in response to the industrial needs for snagging wheels and the polishing of optical equipment and reached \$68.31 per short ton, compared with \$58.60 per ton in 1943. Of interest, too, is the gradually declining value per carat of imports of industrial diamonds, which in 1944 decreased to \$1.79, thus continuing the trend in recent years toward the use of smaller diamonds, particularly in impregnated or bonded cutting and grinding tools.

The total value of exports of natural abrasive materials in 1944 declined to \$2,091,066, a decrease of 41 percent compared with 1943. The value of each class of abrasive exports was less than in 1943, emery and corundum wheels showing the largest percentage of decrease.

Abrasive materials imported for consumption in the United States, 1942-44, by kinds

GENERAL SUMMARY

The record of the sulfur industry during the past 3 years shows the violent changes in production that are characteristic in wartime.

Sicily took the full brunt of the war in 1943, and sulfur output stopped. Since then, as markets and operating supplies have become available, its sulfur industry has slowly and painfully been coming back to life.

Naval blockades and shortages of ships have plagued the big pyrites exporters, such as Spain, Portugal, and Cyprus. In general they have reduced their output to the level of available transportation and in some places have stock-piled products to support the local mining population.

We can only guess at the fluctuations in demand stimulated in Germany by the rain of bombs in 1944. Germany is believed to have had ample supplies of sulfur available from its own resources and those of the occupied countries supplemented by minor purchases in Spain, but destruction of industrial plants undoubtedly reduced consumption. Japanese sulfur and pyrites producers also began to feel the effects of this kind of warfare in 1944.

Many countries that were prewar importers of sulfur and pyrites from distant sources turned in self defense to sulfur-bearing minerals within their own borders or in adjacent countries. No doubt some of these developments will survive the peace, but others will contract or disappear. For example, sales of Chilean native sulfur declined in 1944. On the other hand, Australian utilization of domestic sulfide ores seems likely to continue after the war.

Although official statistics are lacking for most countries, there is evidence that world production of native sulfur increased in 1944, whereas pyrite decreased substantially.

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

In the United States, production of native sulfur, after a sharp decrease in 1943, increased in 1944 to nearly equal the record set in 1942. During the war, consumption has reached a new record annually. By the end of 1942 output had so far exceeded consumption that stocks became unwieldy, and production was reduced to a point slightly below sales. Consequently, in the past 2 years total industry stock has declined 20 percent and at the end of 1944 was at a prewar level.

Although in 1944 the War Production Board was faced with some serious shortages of sulfuric acid, sulfur itself developed no supply problems beyond a few transportation delays. No allocation orders have been applied to sulfur, nor has the Office of Price Administration found it necessary to do more than continue the application of the General Maximum Price Regulation.

POSTWAR OUTLOOK

From the physical standpoint, the domestic sulfur industry has no reconversion problem. Sulfur and pyrites will continue to serve in peace in the same forms as in war. Nor has there been any appreciable expansion in the number of producers in the United States—greater demands have been met by established companies. Compared with the practice in other industries, producer-owned stocks of sulfur seem to be large, but owing to conditions peculiar to the industry they are not abnormal and are not expected to depress the market. Increased competition from Spanish pyrite will be felt on the eastern seaboard, but native sulfur and domestic pyrite appear to be able to hold most of their present consumers.

The principal uncertainties lie in the realm of national and international trade—national prosperity will automatically bring high volume to the sulfur industry. The export market will depend on future trade agreements, monetary-exchange systems, and the degree of national self-sufficiency practiced in the importing nations. Owing to the high quality of American sulfur, its reasonable price, and the wide dispersion of its foreign sales, serious reduction in the export market is very unlikely.

SULFUR

DOMESTIC PRODUCTION

Responding to the needs of peak war production, the output of crude native sulfur in 1944 was 27 percent greater than in 1943 and nearly reached the record tonnage attained in 1942. In response to continued expansion in demand, shipments from the mines were the largest on record—19 percent greater than in 1943. In addition to the sulfur from Frasch-process mines, relatively small quantities were mined in Texas and Colorado for agricultural purposes.

REVIEW BY STATES

Mines in Texas produced 80 percent and Louisiana 20 percent of the native-sulfur output of the United States in 1944.

Sulfur produced and shipped in the United States, 1940-44

Year	Produced (long tons)				Shipped	
	Texas	Louisiana	Other States ¹	Total	Long tons	Approximate value
1940.....	2,212,839	512,935	6,314	2,732,088	2,558,742	\$40,900,000
1941.....	2,596,731	537,620	8,902	3,139,253	3,401,410	54,400,000
1942.....	2,885,621	570,345	4,720	3,460,686	3,128,559	50,100,000

1944.....	2,582,238	635,920	—	3,218,158	3,519,083	56,300,000

¹ 1940 and 1942: California and Utah; 1941: California.*Colorado.*—Thomas Sulphur Co. mined sulfur in Delta County.*Louisiana.*—Sulfur operations in Louisiana were limited to the Grande Ecaille mine of the Freeport Sulphur Co. in Plaquemines Parish. Output increased to 635,920 long tons in 1944.

Texas.—In Texas, the following companies produced crude sulfur in 1944: Duval Texas Sulphur Co. at Orchard Dome, Fort Bend County; Freeport Sulphur Co. at Hoskins Mound, Brazoria County; Jefferson Lake Sulphur Co., Inc., at Clemens Dome, Brazoria County; and the Texas Gulf Sulphur Co. at Boling Dome, Wharton County. The Pecos Orla Sulphur Co. mined sulfur ore at the Michigan Claims in Culberson County. At the end of the year Jefferson Lake Sulphur Co. was rapidly completing building construction at its new mine on Long Point Dome, Fort Bend County; full production is being maintained at Clemens Dome, but depletion of this deposit is anticipated in the relatively near future. The following table was compiled from information issued by the Texas State Comptroller's Office.

Sulfur produced in Texas in 1944, by companies, in long tons

Company	First quarter	Second quarter	Third quarter	Fourth quarter	Total
Texas Gulf Sulphur Co.....	324,449	491,237	544,483	481,939	1,842,108

Total.....	507,635	678,829	729,903	665,871	2,582,238

RECOVERY AS BYPRODUCT

Sulfur is a constituent of many ores that are not mined primarily for their sulfur content. Their beneficiation yields substantial quantities of byproduct pyrite, and this tonnage is included in the pyrites section of this chapter. High-temperature processing of metal sulfides liberates oxides of sulfur that are recovered as sulfuric acid at many plants as a means of eliminating a nuisance as well as for the byproduct value. In 1944, the equivalent of 284,000 tons of sulfur was recovered from the gases of copper and zinc smelters. The following table shows the output of acid at such plants during the past 5 years.

Byproduct sulfuric acid¹ (expressed as 60° B.) produced at copper and zinc plants in the United States, 1940-44, in short tons

	1940	1941	1942	1943	1944
Copper plants ¹	254,025	243,812	265,522	348,832	320,572
Zinc plants.....	586,912	672,177	695,242	846,875	804,010
Total.....	840,937	915,989	960,764	1,195,707	1,124,582

¹ Includes sulfuric acid produced as byproduct at a lead smelter.

Elemental sulfur and its compounds also may be obtained from coke-oven, refinery-still, natural, and other gases. Byproduct elemental sulfur is recovered by the Thylox, Ferrox, and Nickel processes. Plants are situated in Arkansas, Illinois, Maryland, Massachusetts, Michigan, Missouri, New Jersey, New York, Washington, West Virginia, and Wisconsin. Output in 1944 (in terms of 100 percent sulfur) totaled 19,096 long tons, of which 6,466 tons valued at \$262,266 were shipped. Approximately 60 percent was marketed in paste form containing from 35 to 52 percent sulfur, and 40 percent was dried before being sold.

Through the phenolate, phosphate, and Girbotol processes, fuel gases also yield hydrogen sulfide, much of which is subsequently converted to sulfuric acid. In 1944 the hydrogen sulfide recovered contained 21,964 long tons of sulfur. Plants are located in California, New Jersey, and Pennsylvania.

STOCKS

During 1944 producers' stocks declined 8 percent to 4,100,320 long tons, 3,539,715 of which were at the mine and 560,605 at consuming centers, ports, or in transit.

PRICES

Trade journals continued to quote crude sulfur at \$16 per long ton f. o. b. mines in 1944. Throughout the war, sulfur and acid prices have been very stable. From time to time the Office of Price Administration has considered issuing a fixed schedule of prices, but each time investigation showed that such a move was unnecessary and no action was taken.

CONSUMPTION AND USES

In 1944, as in each of the previous 4 years, consumption of sulfur in the United States attained a new record, 15 percent higher than in 1943. A calculation based upon production and change in stock indicates that total sales were approximately 12 percent greater than in 1943.

Total.....	1,848,000	2,239,000	2,471,000	2,532,000	2,870,000

¹ To avoid disclosing estimated consumption of sulfur in direct defense applications, such as military explosives, sulfur so used in 1941-44 is included under "Chemicals."

Sulfur has many uses in elemental form, but about three-fourths is converted to sulfuric acid. In addition to being a very effective reagent in the vast majority of industrial processes that require acid, sulfuric is also the cheapest in most areas. Its wide popularity is indicated in the accompanying table showing the estimates of consumption by industries made by Chemical and Metallurgical Engineering. In comparing these figures with those published in the similar tables in previous years it should be noted that whereas the tonnages were formerly expressed on a 50°B. basis, they are now converted to 100 percent sulfuric acid.

Sulfuric acid (basis 100 percent) consumed in the United States, 1942-44, by industries, in short tons

Miscellaneous.....	350,000	350,000	340,000
Total.....	7,770,000	8,660,000	9,090,000

¹ To avoid disclosing estimated consumption of acid in direct defense applications, such as military explosives, acid so used is combined with "Chemicals."

The over-all increase in consumption in 1944 (5 percent) was fairly evenly distributed over the industries, and only a few registered minor losses. The acid-production capacity of the country has been expanded substantially during the war, but even so the supply was not adequate in 1944; consequently, construction of facilities capable of contributing an additional 550,000 tons of acid annually was authorized by the War Production Board. All the plants built in the United States during the war have been designed to use native sulfur, owing to its greater availability. Some old chamber plants that utilized pyrites have been abandoned. Although consumption in nearly all uses has increased since 1940, one-third of the additional volume has gone into fertilizers and half of it into chemicals, including military explosives. On December 1, 1944, sulfuric acid was placed under Schedule 74 of General Allocation Order M-300 of the War Production Board.

FOREIGN TRADE

The United States supplies a large percentage of the foreign demand for native sulfur. In 1944 exports of sulfur to foreign countries equaled about 21 percent of the total tonnage produced in the United States. The following table shows the distribution, by countries, of these exports. In previous years a substantial tonnage of elemental sulfur was imported into the United States from British Columbia, but in 1944 only a negligible quantity entered.

Our foreign trade in sulfuric acid was nearly balanced as 20,725 short tons were exported and 17,958 tons imported.

¹ Less than 1 ton.**WORLD PRODUCTION**

High production of sulfur in the United States overcame the decline in Italy and elsewhere in 1944. Official statistics are lacking, but it is believed that world production of elemental sulfur, including that derived from gases, totaled about 3,800,000 long tons in 1944.

World production of native sulfur, 1937-44, by countries, in long tons¹

¹ Native sulfur believed to be produced also in China, Cuba, India, Iran, Taiwan, and U. S. S. R., but quantity unknown.² Data not available.³ In addition, 1,050 tons of sulfur rock (40-80 percent sulfur) reported for 1937.⁴ Estimate.⁵ In addition, following quantities of sulfur rock reported—1937: 19,793 tons; 1938: 16,545. Similar data not available for later years.⁶ Production of Sicily for fiscal year ended July 31 of year stated.⁷ The incomplete datum cited is crude sulfur ore; total production and sulfur content are unknown.⁸ Exports.⁹ Estimated sulfur content of ore, excluding sulfur made from pyrites.

Argentina.—In 1944 Argentina continued its efforts to develop an adequate domestic supply of sulfur. Industrias Químicas Nacionales, S. M., a corporation financed by both private and Government capital, had hoped to increase production from its mine and plant south of Socompa sufficiently to approach the national consumption—about 30,000 tons annually. However, these operations are in the Andes, where landslides, transportation difficulties, and other problems peculiar to high altitudes often interfere; consequently, production is reported to have reached only 8,000 metric tons in 1944. A shortage of sulfur developed early in the year, but this was soon relieved by imports from the United States and Chile. In the first 11 months 26,910 tons were imported.

Chile.—Development of a stable and profitable native sulfur industry in Chile is handicapped by high costs growing out of the unfavorable occurrence of the deposits when compared with those in the United States and Italy. Chilean producers enjoyed a temporary increase in demand in 1942 and 1943 when South American consumers found it difficult to obtain American sulfur, but in 1944 exports from Chile declined drastically.

Mexico.—According to official figures, exports of refined sulfur aggregated 1,002 metric tons in 1944.

In past years Mexican sulfur production has come from surface or shallow deposits mined by conventional methods, and output has been small. The possibility of developing larger operations in the future is indicated by explorations in the State of Veracruz. Engineers say that sulfur domes are known in this area, and plans for their exploitation by the Frasch process are under consideration. The organization of two companies that would develop these domes with Government assistance has been reported, and one has begun drilling its first prospect hole.

Sicily.—In the fiscal year 1943–44, the Sicilian sulfur industry sank to nearly complete collapse. Only 31 mines were in spasmodic operation, and production totaled 9,441 metric tons.

In the more normal year 1935–36, output totaled 224,397 metric tons. In that year 106 mines were in operation, 7 of which produced over 10,000 tons each, 13 had capacities of 5,000 to 10,000 tons, 25 could produce 1,000 to 5,000 tons, and 61 less than 1,000 tons.

During the fighting, many of the mines were flooded and much equipment must be replaced before operations can be resumed. At present, power and supplies are scarce and expensive, but some progress has been made in re-equipping the mines, and output for the last 5 months of 1944 increased to 22,556 tons.

When the Allies assumed control of Sicily in 1943, about 25,000 tons of sulfur were found in stock. By the end of 1944, the Allied Commission had exported 19,000 tons to North Africa and 13,000 tons to Great Britain, and stocks were about 24,000 tons. The current price fixed by the Allied Commission is \$45 per ton alongside ship at seaport. Formerly, sulfur sales were handled through the Ufficio Per Le Vendite Dello Zolfo Italiano, a Government organization with headquarters in Rome. A purely Sicilian sales organization, the Ente Zolfi Siciliani, has now been formed to handle the products of Sicilian sulfur mines. Delivery is made to the Consorzio Magazzini Generali, a cooperative warehousing concern, which pays producers 83 percent of the price on delivery and holds the sulfur for disposition

by the sales company. Ente Zolfi Siciliani, a nonprofit organization, divides the proceeds of its sales proportionately among the producers after reimbursing Magazzini Generali for payments already made.

PYRITES

DOMESTIC PRODUCTION

After setting new records in each of the previous 4 years, production of pyrites in the United States declined 2 percent in 1944. Of the total tonnage, 89 percent was classified as fines and the remainder as lump.

Pyrites (ores and concentrates) produced in the United States, 1940-44

Year	Quantity		Value	Year	Quantity		Value
	Gross weight (long tons)	Sulfur content (percent)			Gross weight (long tons)	Sulfur content (percent)	
1940.....	626, 640	41. 8	\$1, 920, 000	1943.....	802, 384	40. 9	\$2, 844, 000
1941.....	645, 257	41. 9	2, 009, 000	1944.....	788, 530	42. 2	2, 598, 000
1942.....	720, 363	42. 6	2, 464, 000				

For many years prices have not been sufficiently attractive to strongly encourage the production of pyrite for sale on the open market. Consequently, domestic production is largely by companies that can utilize the material locally, principally for conversion to acid. In 1944, the producing companies consumed 575,788 long tons, whereas they sold only 212,099 tons.

REVIEW BY STATES

California.—Output from the Hornet mine of the Mountain Copper Co., in Shasta County, made California the second-largest pyrites-producing State in 1944.

Colorado.—The Rico Argentine Mining Co. operated its mine in Dolores County, Colo., in 1944.

Illinois.—At its Atkinson mine in Henry County, the Midland Electric Coal Corp. recovered 8,259 long tons of pyrites (coal brasses). As these occur in the coal as seams or lenses up to 4 inches in thickness, only moderate crushing is required to free them, allowing separation from washer waste, by jigs, of additional salable coal as well as byproduct lump pyrite.

Indiana.—Output of pyrite (coal brasses) by the Snow Hill Coal Corp. at the Talleydale mine in Vigo County increased in 1944.

Montana.—The Anaconda Copper Mining Co. recovered a substantial tonnage of pyrite in 1944 as a byproduct of its copper-plant operations at Anaconda in Deer Lodge County.

New York.—The St. Joseph Lead Co. shipped pyrites from the Balmat mine in St. Lawrence County in 1944.

Pennsylvania.—The Bethlehem Steel Co. produced pyrites in Lebanon County.

Tennessee.—As in past years, Tennessee led all other States in the production of pyrites. Output came from mines in Polk County operated by the Tennessee Copper Co. and was converted by that company to sulfuric acid and iron sinter.

Virginia.—Pyrites were produced by the General Chemical Co. at the Gossan mine to supply its sulfuric acid plant at Pulaski.

Wisconsin.—The Vinegar Hill Zinc Co. recovered pyrites in Grant County and converted them into acid.

FOREIGN TRADE

Prior to the war, pyrite imports commonly ranged between 300,000 and 500,000 long tons annually, most of which came from Spain. As war conditions limited the shipping available to this trade, receipts from Spain declined rapidly. Canada was able to offset the loss for a time, but this tonnage dwindled when the ore body of one of the mines was exhausted in 1943. As ample native sulfur was available in the United States to replace the lost pyrite, there was little incentive to bolster pyrite imports through Government action. All available allied shipping was needed for other services, so imports of Spanish pyrites were carried only in neutral ships in 1944. Importers were in a poor position to compete for even these few bottoms, as prices of pyrite in the United States were too low to assure a profit after payment of wartime ocean freight charges. Consequently, only a few thousand tons of Spanish pyrites entered the United States in 1944, and total imports were 29 percent lower than in 1943.

In peacetime the bulk of the pyrite imported enters various customs districts on the eastern seaboard (principally Philadelphia and Maryland), and, after being burned, much of the cinder is shipped to Wilmington, Del., for recovery of residual metallic products. In 1944 entry was mainly through the Buffalo district. Metal-recovery activities continued on a reduced scale.

WORLD PRODUCTION

Owing to the strategic importance of pyrites in the war industries of many countries, production statistics have been released by comparatively few. Because many of the large pyrite-producing and consuming areas were under direct military attack, it is estimated that world production may not have exceeded 7,000,000 metric tons in 1944.

*World production of pyrites (including cupreous pyrites), 1938, 1942, 1943, and 1944, by countries, in metric tons*¹

¹ In addition to countries listed Belgium, Brazil, China, Chosen, Eire, India, Japan, and U. S. S. R. produced pyrites, but production data are not available.

² Data not available. ³ Slovakia only. ⁴ Estimate. ⁵ Incomplete data.

⁶ Revised estimate; previous data proved to be production of only one mine.

⁷ Exports.

⁸ Average sulfur content of pyrites was 42 percent in 1931, latest year for which such information was available.

⁹ January to June, inclusive.

Australia.—As Australia is distant from the major sources of sulfur she encourages the use of domestic ores. A bounty (27 shillings per ton when imported brimstone costs £6) is paid to producers using Australian minerals. In 1937–38, 462,871 tons of sulfuric acid were produced in Australia, of which 73 percent was made from brimstone, 16 from zinc concentrates, 11 from pyrites, and 0.03 from spent oxide. The brimstone came principally from the United States, but substantial quantities came from Italy and Japan. Acid requirements during the war have been much lower, owing to a shortage of phosphate rock following the loss of Nauru and Ocean Islands. In 1943–44, output was 244,787 tons of acid, of which 33 percent was made from brimstone, 27 from zinc concentrates, 37 from pyrites, and 3 from spent oxide. The trend has therefore been toward greater self-sufficiency. Indications are that the trend will go still farther, as recovery from zinc concentrates was below capacity in 1943–44, and superphosphate companies in Western Australia have contracted to use

pyrite concentrates from Norseman to fill their acid requirements. The average value of sulfur imports for 7 years before the war was £438,000—a substantial and attractive market to producers who have surpluses of sulfide concentrates.²

Brazil.—Although Brazil is rich in most natural resources, it has not developed a domestic source of sulfur. Imports from the United States and Chile have been well-maintained during the war, and no serious shortages occurred. It is possible that Brazil may obtain its sulfur from coal brasses at some future time. To serve the growing iron and steel industry as well as other domestic fuel needs, the Brazilian Government is investigating the possibility of beneficiating pyritiferous coal for the dual purpose of improving its quality and obtaining a pyrite byproduct to supply the nation's sulfur requirements. In addition to extensive laboratory work carried on in Brazil, engineers studied coal-washing practice in the United States in 1944.³

Canada.—Waite Amulet Mines, Ltd., has begun to market pyrite obtained as a byproduct of its metal-mining operations. A newly installed pyrite-concentrating plant began operating early in 1944, and 48,925 tons of pyrite were shipped during the year. At the end of the year sales were averaging about 3,700 gross tons per month.⁴

Cyprus.—In 1944 the pyrites industry on Cyprus was still dormant owing to war conditions.

Norway.—Unofficial but apparently reliable production statistics indicate that war conditions have not reduced Norwegian pyrite production drastically. Output for the war years was given as follows: 1939, 1,024,953 metric tons; 1940, 762,312; 1941, 954,541; 1942, 826,415; and 1943, 800,800. In the first 5 months of 1944 production was maintained at about the same rate as in 1943.

Portugal.—Like the rest of the Iberian pyrites industry, mining in Portugal was reduced to the bare minimum required to keep the mines open and to sustain the miners and their families. Before the war, about 500,000 metric tons were produced annually, of which over 80 percent was exported to France, Belgium, Great Britain, Holland, and French Morocco. During the war, output declined steadily to about 110,000 tons in 1943 and 1944.

In Portugal, pyrites are obtained chiefly from three groups of mines in Baixo Alentjo Province. The S. Domingos group, operated under a concession by a British company, formerly produced about 300,000 tons a year, but in 1944 it was down to a little less than 100,000 tons. The Aljustrel group, operated by a Belgian concern, in normal times produced 250,000 tons annually, but output has diminished to 6,000 tons since the war. The Grandola group, smallest of the three, has produced up to 100,000 tons a year; in 1944, however, only 24,000 tons were produced. Exports must be made in light-tonnage vessels, because the S. Domingos group ships from Pamarao on the Guadiana River, and the other two groups ship from Setubal.

Spain.—Production of pyrites in Spain continued on a reduced basis in 1944; output totaled 511,320 metric tons. The American market was nearly inaccessible, but in the first 11 months Great Britain took 157,771 tons; French Morocco, 13,770; Switzerland, 9,747; Ireland 8,000; and Germany 26,444 tons (compared with

² The Mining Journal (London), vol. 224, No. 5718, March 24, 1945, p. 183.

⁴ The Northern Miner, vol. 31, No. 2, April 5, 1945, p. 14.

43,273 in 1943). In 1943, pyrites were produced in 5 provinces, as follows: Alava, 1,312 metric tons; Huelva, 470,538; Huesca, 113; Murcia, 20,115; and Sevilla, 22,670. In 1944, most of the output came from the Huelva mines of the Rio Tinto Co., Ltd., and the Tharsis Sulphur & Copper Co., Ltd. The Compagnie Française des Pyrites de Huelva, Compañía Buitron, S. A., Union Española de Explosivos, S. A., and Arrendatarios de San Telmo S. A. also were active in Huelva. In Seville Province, producers were Sociedad Española de Minas del Castillo de la Guardas, the Seville Sulphur & Copper Co., Ltd., the Pena Copper Mines, and Sociedad Minera del Guadiana. Union Española de Explosivos also mined in Murcia Province.

Current domestic and export sales are not nearly sufficient to maintain the pyrites industry at its accustomed rate of production, and even at present reduced rates, which serve to support the mining population and maintain the mines and plants, stock piles are being accumulated. Spain hopes to recapture its export markets after the war. Prices of pyrites for export range from 16 to 24 shillings per ton. The freight rate offered on shipments to the United States from Huelva is \$7.50 per ton, a figure that does not attract many ships under present conditions.

Sweden.—Owing to her isolated position during the war, Sweden has had to enlarge her production of pyrites and sulfur. Her needs are being met by expansion of pyrites output in the Boliden area to about 400,000 tons combined with the output of the Falun mines. Possibly 20,000 tons of elemental sulfur are recovered annually from flue gases of the Ronnskar smelter and shale-oil plants.⁵

GENERAL CONDITIONS

Another record for the annual marketed production of domestic phosphate rock was made in 1944, the quantity sold or used by producers reaching 5,376,643 long tons (see fig. 1)—about one-quarter mil-

FIGURE 1.—Marketed production of domestic phosphate rock, 1900-1944.

lion tons above the figure reported for 1943, the previous record. All States except Virginia showed increases. The total value (\$20,856,429) was nearly 2 million dollars greater than in 1943. Mined production was over 5 million tons in 1944. Exports changed their trend from recent years, rising considerably in 1944. Imports increased markedly, rising from 46,505 tons in 1943 to 123,414 tons in 1944. Apparent domestic consumption exceeded 5 million tons. Figures for mined production and stocks for 1944 are not strictly comparable with those for 1943 because of the inclusion in 1943 of considerable quantities of

¹ Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Tennessee brown-rock matrix in the reported figures. The P_2O_5 content of the domestic phosphate rock sold or used in 1944 was 1,739,489 tons.

POSTWAR OUTLOOK

It is natural to expect that, after cessation of hostilities, prewar conditions in the phosphate-rock industry will return, with the reopening of the old markets abroad and a more normal demand for phosphate rock in the United States. However, the world has been completely upset by the greatest war in history, and the organization of the postwar world has not yet been decided upon. Colossal war expenditures by the fighting countries forecast complicated financial

difficulties, with possibly even greater economic instability than in the interval between World Wars I and II. The principal foreign markets for domestic phosphate rock were the Axis nations, whose future is not yet settled. Intense competition in all European markets is to be expected from the high-grade Russian phosphate deposits and from the rejuvenated phosphate-producing industry of French North Africa. These sources are within easy shipping distance of European markets and may be favored by depreciated currencies. Some improvement from the war-depressed condition of our export trade in phosphate rock is to be expected, but domestic producers may obtain less of the foreign market than they held in the prewar years.

The present record domestic consumption is abnormal, as it is based upon an extraordinarily high war-stimulated farm income. Congress, however, has guaranteed the farmers 90 percent of parity for their crops for 2 years; hence farm income may continue at a high level for some time, with concomitant large fertilizer purchases. With later declines from war-increased food demands and high agricultural prices, farm income may be expected to decline, followed by declines in fertilizer consumption and in the sales of phosphate rock for fertilizer manufacture. In the industrial and chemical field the greatly expanded facilities for production of phosphorus brought about by war demands will be excessive for peacetime needs unless new products and new processes are developed.

PRODUCTION

Phosphate rock was mined in 1944 in Florida, Tennessee, Montana, and Idaho and apatite in Virginia. Increased production is reported from Florida and the Western States. The Tennessee figure and that for the total United States mined production are not strictly comparable with those for 1943, because of the inclusion of considerable quantities of washer-grade phosphatic matrix in some of the earlier reports from Tennessee. A more detailed classification called for in the schedules now used has made it possible to eliminate most of this material from the 1944 totals.

Phosphate rock mined in the United States, 1935-44, by States, in long tons

Year	Florida	Tennes- see ¹	West- ern States	United States	Year	Florida	Tennes- see ¹	West- ern States	United States

¹ Includes small quantity of apatite from Virginia.

² Includes small quantity of phosphate rock from South Carolina.

³ Includes some matrix of washer grade.

SALES

The quantity of domestic phosphate rock sold or used by producers reached a new high record in 1944 and exceeded the previous maximum of 1943 by 250,411 long tons. The total value in 1944 was nearly 2 million dollars above that of 1943. The average value per ton of the phosphate rock sold or used was nearly 5 percent greater than in 1943.

1942.....	4,644,240	16,597,492	3.57				

DISTRIBUTION OF SALES

The most popular grades of phosphate rock sold or used by producers in the United States in 1944, according to reports from them, were the 72-percent B. P. L. grade and the 75/74-percent B. P. L. grade. The quantity of phosphate rock containing less than 60 percent B. P. L. sold or used continued to increase and in 1944 formed 12 percent of the total.

In 1944 the quantity of domestic phosphate rock sold or used by producers in the United States for the production of superphosphate is reported to have been slightly larger than in 1943. Increases were also registered in the quantity sold or used for the production of various chemicals and also for direct application to soil. Less is reported to have been used in 1944 than in 1943 for fertilizer filler and for stock and poultry feed.

¹ Bone phosphate of lime.² Figures not available.³ Includes numerous grades of B. P. L. content from 65.9 to 85 percent.⁴ 0.5 percent or less.⁵ Includes phosphate rock used in pig-iron blast furnaces, parting compounds, research, defluorinated phosphate fertilizers, refractories, and other uses.⁶ As reported to Bureau of Mines by domestic producers.

CONSUMPTION

The abnormal rise in the annual apparent consumption of phosphate rock in the United States under war conditions continued in 1944. (See fig. 2.) Again attention is called to the ever-increasing width of

FIGURE 2.—Consumption of phosphate rock in the United States, 1867-1944.

the fluctuations across the curve representing the growth line of domestic consumption and the present position of the consumption far above the normal.

PRICES

Maximum prices for Florida land-pebble phosphate rock and Tennessee brown-rock phosphate were originally established by the Office of Price Administration in October 1942 (Maximum Price Regulation 240). Amendment 3 to this regulation, effective December 3, 1943, increased Tennessee producers' prices 20 cents a ton. These regulations were operative during the first half of 1944. In Revised Maximum Price Regulation 240, effective July 6, 1944, the Office of Price Administration granted an average increase of 20 cents a ton in producers' maximum prices of Florida land-pebble phosphate rock. With this increase there was announced a revision of the regu-

lations covering Florida land pebble, Florida hard rock, and Tennessee brown phosphate rock, but no changes in prices other than that mentioned. Maximum prices were established for Florida hard-rock phosphate.

Ceiling prices per long ton of Florida and Tennessee unground phosphate rock, f. o. b. cars at mines, by grades, effective July 6, 1944¹

Grades—B. P. L. ² content (percent)	Prices			Grades—B. P. L. ² content (percent)	Prices

72/70.....	3.20	\$7.10	5.50				

¹ Office of Price Administration Revised Maximum Price Regulation 240, July 1, 1944, effective July 6, 1944.

² Bone phosphate of lime.

On February 13, 1945, a price increase of 10 cents a ton, at the miners' level, for Tennessee phosphate rock was announced by the Office of Price Administration, to be effective February 17, 1945 (Amendment 1 to Revised Maximum Price Regulation 240—Phosphate Rock). This action is to make no change in retail prices, purchasers absorbing the increase. This addition to the prices is the estimated cost of an increase in wages given by the Fourth Regional War Labor Board with the approval of the Director of Economic Stabilization to four companies engaged in mining and processing Tennessee phosphate rock.

REVIEW BY STATES

Florida.—New records were set in 1944 for the quantities of land pebble and total Florida phosphate rock sold or used (see fig. 3). However, the quantities of both hard and soft rock marketed in 1944 were considerably less than in 1943. The total quantity of phosphate rock sold or used by producers in Florida was 164,302 long tons more than the former record of 1943. The total value of the rock sold or used in 1944 was greater than in 1943 but was still below the 1920 record value. The average values per ton for all types were higher than in 1943.

There were no hard-rock phosphate-mining operations in Florida in 1944. The Dunnellon Phosphate Mining Co. (P. O. Box 157, Savannah, Ga.), a former producer, reports that it made no output and no shipments in 1944 from its mine in Citrus County, near Hernando, that its plant was dismantled at the outbreak of the war in Europe in 1939, and that it will remain inactive for the duration of the war. J. Buttgenbach & Co. (Box 67, Lakeland, Fla.) and C. & J. Camp, Inc., (Box 608, Ocala, Fla.), operating jointly, dried some hard rock from stock at Fernandina, Fla., and exported a considerable quantity. These two companies were preparing a new mine—the Section No. 12 mine near Hernando—for operation but made no production in 1944. This mine was described by Kibler³ late in the year.

³ Kibler, D. B., Jr., Mining and Preparation of Florida Hard-Rock Phosphate: Min. and Met., vol. 25, No. 454, October 1944, pp. 475-476.

The Federal Trade Commission during the year ordered an investigation of the Florida Hard Rock Phosphate Export Association of Savannah, Ga., and the Phosphate Export Association, New York, N. Y., under the Webb-Pomerene law (Export Trade Act) to determine whether they have entered into agreements and engaged in restraint-of-trade activities in violation of law.

In the land-pebble field, the Pembroke Chemical Corp. (Pembroke, Fla.) did not mine or ship during 1944. The seven other companies usually operating in this field—American Cyanamid Co. (Brewster); American Agricultural Chemical Co. (Pierce); Coronet Phosphate Co.

FIGURE 3.—Rate of growth of phosphate rock sold or used by producers, 1933-44, by States.

(Plant City); International Minerals & Chemical Corp. (Mulberry); Phosphate Mining Co. (Nichols); Southern Phosphate Corp. (Ridge-wood); and Swift & Co. Fertilizer Works (Agricola)—mined and shipped land pebble. The Coronet Phosphate Co. is defluorinating phosphate rock and apatite at West Conshohocken, Pa. An article by Fuller and Casler¹⁰ on the mining of land-pebble phosphate rock, and one by Swainson¹¹ on the washing and concentration of the same type of rock appeared late in 1944.

A new Bucyrus-Erie walking dragline excavator, reportedly the largest phosphate dragline ever built, was purchased in 1944 by the International Minerals & Chemical Corp., and is to be installed at its Peace River mine in 1945. This dragline is projected to have a boom of 215 feet with a 20-cubic yard bucket.

Field-test comparisons of colloidal phosphate and superphosphate as sources of phosphorus for potato growing were described.¹²

Tennessee.—According to reports from producing companies, the tonnage of phosphate rock sold or used by Tennessee producers in 1944 (plus a small quantity of apatite from Virginia) was slightly greater than in 1943. The phosphate rock sold or used—all brown rock, except the Virginia apatite and a little blue rock withdrawn from its stocks and used by the Tennessee Valley Authority—was about 15,000 tons greater than in 1943. The total value was likewise greater.

Tennessee brown-rock phosphate was mined in 1944 by the Tennessee Valley Authority (Columbia, Tenn.) and by several private companies: Armour Fertilizer Works (Room 350, Hurt Building, Atlanta, Ga.), Federal Chemical Co. (634 Starks Building, Louisville, Ky.), Harsh Phosphate Co. (Route 4, Murfreesboro Road, Nashville, Tenn.), Hoover & Mason Phosphate Co. (8 South Michigan Ave., Chicago, Ill.), International Minerals & Chemical Corp. (20 North Wacker Drive, Chicago, Ill.), Monsanto Chemical Co. (1700 South Second Street, St. Louis, Mo.), and Virginia-Carolina Chemical Corp. (Richmond, Va.).

The treatment of phosphate rock in Tennessee was described in articles by Grissom ¹³ and by Wustrack. ¹⁴

According to the annual report of the Tennessee Valley Authority for the fiscal year ended June 30, 1944, a total of 319,000 tons of phosphatic raw materials was received at Muscle Shoals from Tennessee during the year, more than half of which came from the TVA Columbia (Tennessee) field phosphate plants. These plants recovered nearly 203,000 tons of phosphate sands, of which 165,500 tons were shipped to the furnaces at Muscle Shoals, where the nodulizing kilns produced

¹³ Grissom, R. J., Mining and Washing Phosphate Rock in Tennessee: *Min. and Met.*, vol. 25, No. 454, October 1944, pp. 477-480.

¹⁴ Wustrack, O. H., Phosphate Production Problems: *Rock Products*, vol. 47, No. 11, November 1944, pp. 52-53, 55; No. 12, December 1944, pp. 60-61, 109-110, 129; vol. 48, No. 1, January 1945, pp. 196-197, 221-223; No. 2, February 1945, pp. 82, 84, and 99.

189,000 tons of nodules for the furnaces—an increase of 15 percent over the previous fiscal year. No additional phosphate lands were acquired during the fiscal year, but options were taken on three tracts in Williamson County containing an estimated 1,309,000 tons of phosphatic matrix.

The output of elemental phosphorus increased 29 percent from 18,900 tons in the fiscal year 1943 to 24,438 tons in 1944, and shipments for direct military use increased from 12,350 tons to more than 19,000. Installation was begun of a new and slightly larger furnace to produce phosphorus to replace the last unit which produced phosphoric acid, so that the total output of the plant could be used for military phosphorus.

Over-all production of concentrated superphosphate and calcium metaphosphate decreased markedly from that of the previous year owing to increased demands for elemental phosphorus by the Chemical Warfare Service. Less than 48,000 tons of the triple superphosphate were produced compared with the fiscal year 1943 production of 60,200 tons. Production of calcium metaphosphate dropped from 7,300 to 2,900 tons. Shipments of triple superphosphate from the Muscle Shoals plant totaled about 51,900 tons and of calcium metaphosphate about 1,000 tons. TVA also produced about 9,000 tons of dicalcium phosphate, to help meet the shortage of phosphate for stock feed, in a plant placed in operation in October 1943.

Late in the fiscal year TVA began construction of a large plant in the Tennessee phosphate field to produce, by a fuel-fired furnace process, fused defluorinated tricalcium phosphate, a material containing about 29 percent P_2O_5 , and suitable for either fertilizer or stock-feed use. In the fiscal year 1944 the pilot plant produced more than 1,000 tons of this product, of which 325 tons were further processed to a form suitable for animal-feed supplement.

There was a great increase in 1944 in production and distribution of granulated calcium silicate slag from the electric furnaces. This slag is of value as a liming material and soil conditioner and in addition contains a small amount of phosphate plant food. Production was 220,000 tons in 1944, and about 243,000 tons were shipped for agricultural use. About 1,200 tons of byproduct potash-phosphorus furnace dust were produced and 500 tons distributed for use in the test-demonstration programs. Production of byproduct ferrophosphorus totaled 1,000 tons.

Miller¹⁵ has described recently the phosphate operations of the Tennessee Valley Authority.

Tennessee phosphate rock (including sintered matrix) sold or used by producers, 1940-44

[Includes apatite from Virginia]

¹ Includes small quantity of blue rock.

¹⁵ Miller, A. M., *Phosphate Activities of the Tennessee Valley Authority: Min. and Met.* vol. 25. No. 454, October 1944, pp. 492-494.

Virginia.—In 1944 apatite was produced as usual from the Piney River nelsonite deposit. In the early part of the year this property was operated by the Virginia Chemical Corp., a wholly owned subsidiary of Interchemical Corp. Later, after several reported changes in ownership, the Calco Chemical Division of the American Cyanamid Co. acquired the property, which became a unit of that division.

A considerable quantity of apatite from this deposit was defluorinated by the Coronet Phosphate Co. (19 Rector St., New York 6, N. Y.) at the Valley Forge cement plant at West Conshohocken, Pa., for use as feed amendment.

FIGURE 4.—Idaho and Montana phosphate rock sold or used by producers, 1933-44.

Western States.—A new high record for phosphate-rock production in the Western States was set in 1944, the marketed production reaching 298,999 long tons (with a P_2O_5 content of 95,767 tons). The production in 1944 came from Idaho and Montana; Utah was inactive.

Idaho rock sold or used in 1944 (112,565 tons with 35,804 tons P_2O_5 content) was still below the record production of 1942 (114,079 tons). The average P_2O_5 content was 31.80 percent. The same two companies were active in this State in 1944 as in 1943 and 1942. By far the larger of these—the Anaconda Copper Mining Co.—operated its No. 3 mine at Conda, Caribou County. Most of the Conda shipments in 1944 went to Anaconda, Mont., for conversion to superphosphate. Much smaller quantities were used for the manufacture of phosphate chemicals, for direct application to soil, for stock and poultry feed, and for fertilizer filler. Some was exported for acidulating. The other producer (the Teton Phosphate Co., Boise, Idaho)

mined phosphate rock from its Bennington mine in Bear Lake County near Montpelier. This material was ground in the company plant and sold for direct application to soil.

Montana was the largest phosphate-rock producer of the Western States group in 1944, as in recent years, its lead in phosphate rock sold or used over Idaho increasing to 73,869 tons. Its total marketed output in 1944 (186,434 tons with a P_2O_5 content of 59,963 tons) exceeded its record of 1942 (150,402 tons) by 24 percent; the average P_2O_5 content was 32.16 percent. Three mining companies operated in the State in 1944. The Montana Phosphate Products Co. of Trail, British Columbia—largest producer in 1944 in the Western States—operated its Anderson, Graveley, and Anaconda mines and also its leases (Great Falls 076740, 081920, 077348, and 076890) in Powell County, Mont. Most of the mined product was exported to the Consolidated Mining & Smelting Co. at Trail, but a considerable quantity was sold in the United States. The International Minerals & Chemical Corp., which in 1942 acquired the Federal lease of the North-western Improvement Co. (St. Paul, Minn.), in the Douglas Creek area, Granite County, Mont., carried on considerable development work at the mine in 1944. It mined a few thousand tons of phosphate rock and treated it in a large test mill recently erected at Sherryl, on the Philipsburg branch of the Northern Pacific Railway about 7 miles from the mine, producing a considerable tonnage of higher-grade concentrates. However, no sales or shipments of the material were made in 1944. Lee H. Skeels, trustee for Soluble Phosphates, Ltd., Maxville, Granite County, Mont., mined a small tonnage at the mine near Maxville in 1944 but made no shipments during the year.

No phosphate rock was produced in Utah in 1944. The Garfield Chemical & Manufacturing Corp., Salt Lake City, Utah, which mined and shipped phosphate rock in 1942 from a Federal lease near Spanish Fork, Utah County, for use in pig-iron blast furnaces, made no production in 1943 or 1944.

Some interest was shown during the year in phosphate-rock deposits near Cokeville and in the Wind River Mountains, Wyoming.

Several articles have appeared recently descriptive of phosphate-rock deposits and industry of the Western States.¹⁶

Several articles relating to the superphosphates industry appeared in 1944.¹⁹

BASIC SLAG

No recent figures for production of basic slag are available for the United States or for any foreign country. None was imported into the United States in 1944.

GENERAL CONDITIONS

Mined production and sales of talc, pyrophyllite, and ground soapstone declined in 1944 from the high levels of 1943, according to reports from the producers. The total value of sales was likewise

FIGURE 1.—Sales of domestic talc, pyrophyllite, and ground soapstone, 1934-44.

slightly less than the record high value of 1943. (See fig. 1.) Only sales of crude material increased either in quantity or value. All classes of imports increased in 1944 over 1943 in both quantity and

¹ Soapstone sold in slabs or blocks is included in the chapter on Stone.

value. Exports of "talc, steatite, soapstone, and pyrophyllite, crude and ground" were higher in quantity but lower in value.

Pyrophyllite is included with talc in this chapter because of its resemblance to talc in certain physical properties and because it is interchangeable with talc in some uses, although during recent years certain specialized uses for pyrophyllite have been developed. It is a hydrous aluminum silicate, whereas talc is a hydrous magnesium silicate. Production and sales figures for pyrophyllite for 3 years are now available.

¹ In 1943: Mined, 64,198 short tons. Sold—crude, 5,432 tons, \$34,306; ground, 56,710 tons, \$460,485; total, 62,142 tons, \$494,791. In 1944: Mined, 67,252 short tons. Sold—crude, 5,083 tons, \$52,343; ground, 60,560 tons, \$504,739; total, 66,243 tons, \$557,082.

² Data not available.

³ Includes pinites from Nevada.

⁴ Exclusive of "manufactures, n. s. p. f., except toilet preparations," as follows: 1943, \$20; 1944, \$25. Quantities not available.

⁵ Quantity not recorded.

Thirteen States reported sales of talc, pyrophyllite, or ground soapstone in 1944. Texas was the only new producer. The Eastern States furnished the greater part of the total domestic sales in 1944, and most of the remainder came from the Southwest—southeastern California and southwestern Nevada.

The steatite talc situation eased during the year, and at the end of the year there was a considerable stock pile and no shortage for current needs. However, the supply situation of fibrous talc, greatly needed for camouflage paints, became acute. The lower-grade talcs were also in short supply. A shortage of block talc for metal workers' marking crayons was relieved by increased production of extruded talc crayons.

A topographic and geologic map of the Gouverneur talc district, New York, the largest talc-producing district in the United States, was issued by the Geological Survey early in 1945. An area about 10 miles long and 2½ miles wide is shown in which highly metamorphosed gneisses and marbles of the Grenville series (pre-Cambrian) are in-

truded by pre-Cambrian granites and gabbros. Zones of tremolite-talc rock occur in the Grenville marble.

Descriptions of talc deposits in Montana and Vermont were published during the year.¹

Pyrophyllite was in short supply early in 1944 owing to the increased demand for it as an insecticide carrier, but increased production facilities relieved the situation later in the year.

POSTWAR OUTLOOK

The return to peacetime conditions after the cessation of World War II undoubtedly will reduce the domestic demand for talc, pyrophyllite, and ground soapstone. There will also be changes in importance of the relative sources of supply. Domestic production may be expected to be less and imports greater, but probably not sufficiently so as to offset the decline in domestic production. Sales for certain war-stimulated uses—such as for nonreflecting paints for ship camouflage, for insecticides for foreign service, for foundry facing, and for metal-workers' crayons for the iron and steel industry—may drop considerably. Other newly developed wartime uses applicable to peacetime conditions may help to maintain sales. War-developed extruded-talc metal-workers' crayons, however, although supplementing sawed crayons in wartime, could cut into the peacetime demand for crayons of that type.

According to Newcomb²:

Steatite may replace mica in electronic equipment. Improved production methods in civilian industries will find many new applications for electronic controls, so that postwar demand for steatite may reasonably be expected to exceed the prewar rate of production. An annual demand for 6 or 7 million dollars worth of steatite is a realistic estimate.

Only one producing company is as yet handling talc by flotation processes to increase the grade of the product, but other companies are reported as showing an interest in flotation, and the beneficiation of domestic talcs to make them suitable for radio insulators may yet form an important source of steatite talc.

Pyrophyllite is reported to be an ideal carrier or diluent for the chemical DDT for insecticides in typhus areas, and for rotenone, pyrethrum, and nicotine in the manufacture of agricultural insecticides. Its use in this application probably will increase when the active ingredients become available.

With the end of the war in Europe, import trade in talc of steatite and cosmetic grades from various European countries undoubtedly will revive further. (See fig. 2.) Stoppage of the Asiatic phase of the war will likewise release Manchurian and other Asiatic talcs for importation into the United States.

SALES

In 1944 both the quantity and value of domestic talc, pyrophyllite, and ground soapstone sold or used were less than in 1943, according to the reports of the producers to the Bureau of Mines; the average value of the material, however, was slightly higher.

² Includes pinites from Nevada.

Sales by States.—In 1944 New York continued to be the leading producer by a wide margin, although sales were less than in 1943. The total quantity of North Carolina talc, pyrophyllite, and ground soapstone sold or used in 1944 was greater than the previous high of 1943. Sales of California rock exceeded the previous record of 1941. North Carolina was the principal State marketing pyrophyllite, but small quantities are reported to have come from California and Nevada.

² Includes pinites.

³ 1943: Maryland, Montana, New Mexico, Pennsylvania, and Virginia. 1944: Montana, New Mexico, New York, Pennsylvania, Texas, and Virginia.

MARKETS

Six industries—paint, ceramics, rubber, roofing, paper, and insecticides—took 72 percent of the domestic sales of talc, pyrophyllite, and ground soapstone in 1944, according to reports from producers to the Bureau of Mines. Of these six, as tabulated, the rubber industry alone showed percentage and quantitative increases. Other uses than those titled in the table showed a marked increase over 1943. The quantity for which uses were not reported was also larger.

Talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1943-44, by uses

Use	1943		1944	
	Short tons	Percent of total	Short tons	Percent of total

¹ Less than 0.5 percent.

² 1943: Chemical war service, refractory, plaster, insulation, bleaching, mine dust, textile, and other minor uses; 1944: Chemical war service, refractory, plaster, plastics, bleaching, textile, and other minor uses.

³ Includes plinite.

PRICES

Quoted prices on ground domestic talc per ton, f. o. b. works, were unchanged from those given in the Talc, Pyrophyllite, and Ground Soapstone chapter in Minerals Yearbook, 1942 (p. 1385). According to the Oil, Paint and Drug Reporter of May 14, 1945, these prices were:

California: \$17.50 to \$43.

New York: Fibrous, coarse, off-color, \$13.

Fine, 325-mesh, 93 to 94 percent, \$13 to \$18; 98 to 99.5 percent, \$15.25 to \$19.25; 99.85 to 99.95, \$17 to \$21.

Pennsylvania: \$11 to \$13.50.

Vermont: \$14.

Canadian talc, bags, carlots, per ton, \$24 to \$30.

The prices on pyrophyllite have changed slightly from 1943. According to the same journal these were, in May 1945: Standard, 200-mesh, carlots, bulk, mines, per ton, \$10 to \$11.50; 325-mesh, same basis, \$13.00 to \$13.90; No. 3, 200-mesh, carlots, mines, \$9.50; 325-mesh, same basis, \$11.50.

The average values of all grades of talc, pyrophyllite, and ground soapstone in the past 5 years, as reported to the Bureau of Mines by producers, are given in the table under Sales.

Specific dollar-and-cent ceiling prices for four grades of crude talc produced in Esmeralda County, Nev., announced by the Office of Price Administration on November 13, 1944, became effective on November 16, 1944 (Amendment 62 to Order A-1 under Maximum

Price Regulation 188—effective November 16, 1944). The prices established, based as nearly as possible on price levels existing in March 1942, were:

	Maximum price per ton, f.o.b. Zurich, Sw.
Grades:	
No. 1.—Selected Cosmetic Talc.....	\$15.25
No. 2.—Mine-Run White Talc.....	13.00
No. 3.—Mine-Run Talc (Blue or Blue and White Mix).....	10.25
No. 4.—Talc Filler (Blue Talc).....	8.00

Prices of talc produced in other parts of the country are governed by Maximum Price Regulation 188, which has a base pricing period of March 1942.

Producers of pyrophyllite who could qualify as being unable to make and sell their product at existing maximum prices were provided by the Office of Price Administration with a method of applying for price adjustment after August 24, 1944. (Amendment 17 and Order 50 modifying Order A-2 under Maximum Price Regulation 188—both effective August 24, 1944.) The Office of Price Administration was to determine to what extent, if any, increases resulting from adjusted producers' ceilings may be passed on by resellers of the commodity.

DEVELOPMENTS IN THE INDUSTRY

According to Newcomb,³ there are now 27 steatite-insulator manufacturing plants as compared with 5 before the war. In spite of the fact that the manufacture of steatite insulators requires much closer tolerances and radically different production technique, a number of plants normally making electrical porcelain, wall tile, and other products have successfully converted to their manufacture. These plant conversions, involving relatively little new equipment, have made possible the production of 21.6 million dollars worth of steatite products in 1943 as compared with only 1.6 million dollars worth in 1939.

The Tennessee Valley Authority reports⁴ that it

developed a method for making talc pencils by bonding waste talc. The pencils are in demand for metal marking, particularly by the Navy in its shipbuilding program and by the steel industry. Hitherto, talc pencils could be sawed only from solid blocks and less than 5 percent of the producers' run-of-mine talc could be used.

Wollastonite (CaSiO_3) was suggested as a possible substitute for talc as a mineral filler in a letter from R. Van L. Burnham dated November 4, 1944. A deposit in Essex County, N. Y., was described early in 1944.⁵

Carl⁶ has described tests on the firing and heating properties of high- and low-grade block talc. Talc samples from three States—California, Maryland, and Montana—and two foreign countries were

⁶ Carl, H. F., *Study of Firing Failure in Massive Talc*: Bureau of Mines Rpt. of Investigation 3800, 1945, 9 pp.

studied for composition, texture, grain size, and structure, and their behavior under firing conditions in an electric furnace was observed.

Heizer and Treganza⁷ have described in detail the sources of steatite, talc, and soapstone used by the Indians of California and the varied uses to which these materials were put.

Burnham and Tuttle⁸ have discussed the effect of composition on the ability of glazed dishes to withstand thermal-shock treatment ordinarily received in cooking. Of the bodies studied, the best results were obtained with those containing approximately 10 percent of New York talc and also with a small amount of calcined clay substituted for potters' flint.

Lamar⁹ has correlated the differential shrinkage of fired steatite pieces with the particle shape of the raw talc used in their manufacture. It was found that the more irregular in shape the talc particles the greater the differential shrinkage, and a method is given for assigning arithmetical values ("specific shape factors") to various particle shapes, depending on their deviation from sphericity.

Science News Letter¹⁰ reports that talc is being used as a firebox lining in boilers and locomotives in the Soviet Union instead of the customary firebrick.

The procedure used by the Eastern Magnesia Talc Co. in the flotation of talc in its mill at Johnson, Vt., was described by Franz.¹¹

Experiments described by White¹² are said to

indicate that, although wide variations in the particle size distribution of steatite talcs have a bearing on the firing shrinkage when the talc is incorporated in a body, the differences in grinding obtained in commercial talcs are not of great importance when proper milling practice is employed.

The laboratory and plant procedures used for the control of steatite raw material and the talc-blending system at the plant of the Stupakoff Ceramic & Manufacturing Co., Latrobe, Pa., was described by Staley, Prescott, and Long.¹³

• FOREIGN TRADE ¹⁴

Imports.—The declining trends of recent years in the quantity and value of total imports of talc, steatite, or soapstone, and French chalk was reversed in 1944, and increases are reported not only in the totals but also in all of the reported classes. As usual, the imports were largely of materials "ground, washed, powdered, or pulverized, except toilet preparations." Canada was the chief source of the ground material, and India of the other classes. (See fig. 2.)

¹ United Kingdom of Great Britain and Northern Ireland.

Exports.—The quantity of "talc, steatite, soapstone, and pyrophyllite, crude and ground," exported from the United States in 1944 is stated to have been slightly greater than in 1943 but did not quite reach the all-time record of 1941. The value, however, was less than in 1943. The value of "powders—talcum (in packages), face and compact" exported in 1944 was again reported to exceed a million dollars.

Talcum and other powders exported from the United States, 1940-44

WORLD PRODUCTION

Only a few figures for the production of talc, pyrophyllite, and ground soapstone, in various countries in recent years are yet available. Such as are obtainable are shown in the following table.

World production of talc, pyrophyllite, and soapstone, 1937-44, by countries, in metric tons¹

¹ In addition to countries listed talc or pyrophyllite is reported produced in Brazil, Bulgaria, Chile, Madagascar, New Zealand, and U. S. R. R., but data on production are not available.

² Data not available.

³ Excludes soapstone, which is reported only by value and was as follows: 1937, \$40,513; 1938, \$35,038; 1939, \$41,471; 1944, \$186,261. Soapstone is sold in the form of both blocks and powder.

⁴ January to September, inclusive.

⁵ Includes steatite, as follows:—1937: 500 tons; 1938: 3,480; 1939: 5,545; 1940: 17,191; 1941: 18,948; 1942: 24,859; 1943: 9,741 tons.

⁶ January to June, inclusive.

⁷ Talc, pyrophyllite, and ground soapstone sold by producers; includes also pinit in 1940, 1941, 1942, and 1944.

⁸ Estimate.

Canada.—Developments in the Canadian talc and soapstone industry in 1943 have been described as follows:¹⁵

¹⁵ Canada Department of Trade and Commerce, Dominion Bureau of Statistics, Mining, Metallurgical, and Chemical Branch, The Talc and Soapstone Industry, 1943: Ottawa, Canada, 1944. Data largely from report, Talc and Soapstone in 1943, by Bureau of Mines, Ottawa, Canada.

Mine shipments of soapstone and talc reported in 1943 by operators in the province of Quebec amounted to 14,204 tons worth \$135,469. Production of the higher grades of talc in Canada is confined chiefly to the province of Ontario, and the 1943 shipments totaling 11,959 tons, valued at \$131,216, were made almost entirely from a deposit located near Madoc, Hastings County. Included in the Ontario output was a relatively small tonnage of talc obtained from a property situated near Ompah in Frontenac County. In British Columbia, crude talc imported from the United States was treated in a Vancouver mill. From October to December development work was carried on at a talc deposit located at Red Mountain in the Kootenay National Park of British Columbia; this operation is known as the Lava Talc Project and was conducted by the Wartime Metals Corp., a trial shipment was made to the United States [Foreign] Economic Administration.

* * * * *

During 1943 there were eight firms reported as active in the industry, five in the province of Quebec, two in Ontario, and one in British Columbia; of these, six made commercial shipments. * * *

Annual production of ground talc in Canada in the 5-year period 1939-43, inclusive, ranged from 16,000 to 32,000 tons, these figures including also material classed in the statistical records as soapstone, part of which was ground in mills other than those of primary producers. All of the output came from Ontario and Quebec.

Most of the material from Ontario consists of white, foliated talc, which occurs as veins in crystalline dolomitic limestone of the Madoc area, Hastings County, where an established talc industry has existed for the past 40 years. Total output from the Madoc area to the end of 1943 is about 400,000 tons. Since 1937, Canada Talc, Ltd., operating the Conley and Henderson mines, has been the only important producer. W. C. Spry & Co., in recent years has been milling a small tonnage of finely schistose, cream-colored talc in the plant of Canada Slate Products, about a mile north of Madoc. The crude rock is trucked in from a deposit near Ompah, in Frontenac County, 65 miles distant.

In Quebec, the talc produced is also of the foliated type, but it occurs in bands in highly metamorphosed basic rocks, mainly serpentine and pyroxenite, and is often associated with bodies of soapstone, an impure talcose rock. It contains much iron, and varies rather widely in carbonate content. It yields a slightly off-color, gray powder, and is used chiefly in the rubber, paper, and roofing trades. The entire production is obtained from the Eastern Townships, mainly from the Thetford Mines area, and there are also a mine and a mill at Highwater close to the Vermont boundary. All of Canada's output of sawn soapstone blocks, sold chiefly for use in the alkali recovery furnaces of domestic kraft mills, and also of talc crayons, comes from the Thetford Mines area. Some of the sawing dust from these operations is sold to domestic roofing firms, and a large tonnage of quarry and sawing waste is shipped to the grinding plant of Pulverized Products, Limited, 4820 Fourth Avenue, Rosemount, Montreal.

* * * * *

Many grades of ground talc are marketed, and the price range is wide. Value is dependent upon purity (determined by freedom from lime and gritty or iron-bearing substances, slip, and color), particle shape, and fineness of grinding, the specifications of which vary in the different consuming industries. Roofing and foundry talcs are the cheapest grades, the trades in these being satisfied with coarser, gray or off-color material, often soapstone powder or sawing dust, which sells at about \$5 to \$7 a ton, f. o. b. rail. Domestic gray talc, suitable for rubber and paper use, sold in 1943 for an average of \$7.50 to \$9 per ton. White talc from the Madoc area was quoted at \$8 to \$10 for the coarser grades, \$12 to \$18 for finer mesh sizes, and \$44 for minus 400-mesh material.

A detailed description of the mining and milling of talc by Canada Talc, Ltd., in the Madoc (Ontario) district was published late in 1944,¹⁶ and a description of the Broughton soapstone quarry in the Thetford Mines district of the Province of Quebec in March 1945.¹⁷ The manufacturing methods of the new Canadian Steatite Co., Ltd., plant at Georgetown, Ontario, using California talc, are described by Phillips and Rue.¹⁸

FLUORSPAR

SUMMARY

Impressive as was the performance in 1943, when 405,600 tons of finished fluorspar were produced, operators bettered that record by producing 2 percent more in 1944—an amount slightly larger than the unprecedented consumption, which for the first time exceeded 400,000 tons. Finished production and shipments (413,700 and 413,781 short tons, respectively) in 1944 were each 2 percent greater than in 1943, the previous record year. Moreover, finished production and shipments were each 1 percent greater than consumption, which was 5 percent more than in 1943. Although Illinois shipments declined 11 percent from the all-time high established in 1943, the State not only maintained its rank as the chief producer in 1944 but supplied 43 percent of the total shipments. After declining for two successive years, shipments from Kentucky turned slightly upward. However, Colorado, New Mexico, Texas, and Utah established new records. Shipments by river or river-rail (69,536 tons) were 39 percent more than in 1943, but lacked 12 percent of equaling the all-time high of 1942. Receipts of foreign fluorspar in 1944 also established a new record, exceeding by 22 percent the previous peak of 1926. Exports—usually small—were insignificant in 1944 and totaled only 1,980 tons.

The Government stock-pile objective of 200,000 tons of fluorspar was approaching attainment, and about 154,000 tons had been delivered toward that goal at the close of 1944; however, of this amount 24,100 tons have been disposed of, leaving a balance of 129,900 tons on December 31. The disposal of Government stocks of strategic minerals, which include fluorspar, is covered in the Surplus Property Act of 1944, Public No. 457, 78th Congress, sec. 22 (a), approved October 3, 1944, from which the following is quoted:

All Government-owned accumulations of strategic minerals and metals, including those owned by any Government corporation, shall be transferred by

¹ Figures on imports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce; those on exports of fluorspar supplied by the producers.

the owning agency, when determined to be surplus pursuant to this Act, to the account of the Treasury Procurement Division and shall be added to the stock pile authorized by the Act of June 7, 1939 (53 Stat. 811), as amended, and shall be subject to its provisions: *Provided*, That contractor inventory shall be so transferred only when the owning agency has taken possession of and determined such inventory to be surplus. * * *

Late in 1944 Kentucky fluorspar operators, upon formal application to and approval by the War Labor Board, were permitted to equalize wage rates with Illinois. The established wage scale in Kentucky is 10 cents an hour less than in Illinois.

The monthly production of metallurgical-grade fluorspar exceeded requirements during most of 1944, and because of the reasonably satisfactory supply and demand relationship the War Production Board on August 12 discontinued the restricted shipping plan in effect since January 1, 1943. Moreover, the restriction on the sale or delivery of standard metallurgical-grade fluorspar, although not rescinded, was relaxed during the latter half of 1944.

Salient statistics of fluorspar in the United States, 1935-44, in short tons

Year	Shipments from domestic mines	Foreign trade		Consumption	Stocks at end of year

¹ Finished fluorspar only.

Despite the improved supply-demand position of metallurgical-grade fluorspar in 1944, the domestic steel industry, as in 1943, continued to practice conservation and to study the use of substitutes. The average consumption of fluorspar per long ton of basic open-hearth steel produced dropped from 5.9 pounds in 1943 to 5.7 pounds in 1944. The smaller consumption at steel plants was due to conservation measures, to the use of better-grade fluorspar, to a decline in production of alloy steel, and to the increased use of roll scale; but some substitutes, such as topaz, ilmenite, and salt, were also used in 1944.

According to Steel: ²

Aluminum dross as a substitute for fluorspar affords no advantage. One operator experimenting with salt as a fluorspar substitute found that evaporated salt passed off in fumes, coating the furnace on the outgoing end. Cattle salt fumes off as fast as evaporated. No 2. rock salt gave slightly better results. Recommended practice was the use of 75 percent fluorspar and 25 percent salt.

Although no bauxite is known to have been used as a substitute for fluorspar in the United States, it has replaced fluorspar as a flux in the open-hearth steel works at Port Kembla, Australia. Obtained in

² Steel, Open Hearth and Blast Furnace Groups Set Attendance Record: Vol. 114, No. 18, May 1, 1944, p. 95.

pisolitic form, it is cheap but only about one-third as effective as fluorspar.³ The quantity of bauxite used does not exceed 2 pounds per ton of ingots.

According to Reinartz:⁴

It has been found that, under proper supervision, production (steel) can be increased by the use of slag-control methods because of the more efficient use of smaller charges of flux. This practice will continue to be improved in post-war days.

Production of ceramic-grade fluorspar was again adequate to meet requirements. However, monthly consumption of acid-grade advanced almost steadily during 1944, and as production lagged behind consumption the supply position became worse during the latter part of the year. Moreover, it developed that some of the fluorspar furnished proved unsatisfactory for use in making anhydrous hydrofluoric acid because of excessive sulfur, which could not be coped with in the acid-manufacturing plants. As a result of the unsatisfactory quality of some of the acid-grade shipped, part of the stocks at consuming plants will require further milling before being suitable for the manufacture of anhydrous hydrofluoric acid. To overcome the complaints of inferior quality, steps were taken by such domestic producers to remove the sulfur. The shortage in production was relieved considerably by milling to acid grade some of the Mexican fluorspar in the Government stock pile. The Mexican fluorspar, being of much higher grade than domestic milling ore, lends itself to a higher recovery. Although some flotation concentrates were received from Newfoundland, the product contained excessive moisture which will be removed by drying at a consumer's plant.

Deliveries of fluorspar to consumers in the United States totaled 398,916 short tons in 1944 (387,405 tons from domestic mines, 3,696 tons from Government stock piles, and 7,815 tons from foreign sources); in addition, 24,396 tons of finished fluorspar from domestic mines were delivered to Government stock piles. In 1943 deliveries to consumers totaled 404,658 tons (388,902 tons from domestic mines and 15,756 tons from foreign sources); in addition, 8,070 tons of finished fluorspar from domestic mines were delivered to Government stock piles. Total deliveries to steel plants in the United States decreased to 221,000 tons from 236,425 tons in 1943, but those to hydrofluoric acid plants advanced to 126,991 tons from 123,820 tons; sales to the glass and enamel trades increased substantially.

Maximum base prices of \$30 to \$33 a short ton for metallurgical-grade fluorspar and of \$37 a ton for ceramic and acid grades, established by the Office of Price Administration on July 1, 1943, continued in effect throughout 1944. However, because of the improved supply-demand relationship of metallurgical-grade fluorspar, the selling price was depressed toward the end of the year.

The average composite selling price (\$30.60 a short ton) of all grades of fluorspar (both domestic and foreign) delivered to consumers in the United States was \$1.25 more than in 1943 (\$29.35). The average selling price of all grades of domestic fluorspar shipped in 1944 (\$30.22) established a new peak and was \$1.15 greater than the previous high of 1943. The average selling price f. o. b. Illinois-Kentucky mines, of metallurgical-grade fluorspar shipped to domestic

³ London Mining Journal, vol. 223, No. 5706, Dec. 30, 1944, p. 807.

⁴ Reinartz, L. F., Open-Hearth Steelmaking: Metals and Alloys, vol. 21, No. 1, January 1945, p. 111.

steel plants was \$29.73 a ton (\$28.69 in 1943) and of that shipped to domestic manufacturers of hydrofluoric acid \$36.51 (\$33.86 in 1943).

The total quantity of fluorspar shipped in and imported into the United States from about 1870 through 1944 was approximately 7,226,000 short tons, comprising 6,029,000 tons from domestic mines and 1,197,000 tons from foreign sources. It is noteworthy that, of the total domestic shipments, 1,917,153 tons (32 percent) were shipped during the past 6 years (1939-44).

POSTWAR OUTLOOK

The fluorspar industry will emerge from the war with a demand substantially greater than that during prewar years because of new uses discovered during the war and a growing demand for some of the older uses. However, the possibilities of large imports after the war are a serious threat to the domestic industry, owing to the recent opening of deposits in Mexico, Newfoundland, and Spain, where future production will depend largely on access to United States markets.

Possible substitutes for fluorspar as a flux in steel manufacture have been under study, but so far as known none has been found as efficient for this purpose as fluorspar. Consequently, as heretofore, the steel industry will continue to be the chief consumer of fluorspar. However, some of the conservation measures effected during the war doubtless will be continued. A large expansion in the postwar demand for acid-grade fluorspar, as compared with prewar requirements, will result from the new uses for hydrofluoric acid discovered during the war and from a growing demand in some of its older uses. Two outstanding wartime developments, which have important peacetime possibilities, are the anhydrous hydrofluoric acid alkylation process in aviation-gasoline manufacture and the aerosol insecticide bomb, which uses Freon as a propellant. A greatly increased future demand is anticipated for Freon, used as refrigerant in household and commercial refrigeration plants, air-conditioning systems, and frozen-food lockers. A new unannounced use for hydrofluoric acid, which may rival Freon in making demands on the industry for hydrofluoric acid, has been rumored. A further future demand for fluorspar would develop should studies now under way prove that the addition of fluorine salts to drinking water prevents tooth decay without objectionable effects, such as tooth discoloration. The peacetime requirements of fluorspar for the glass industry, it is believed, will exceed those immediately preceding the war. With respect to the enamel trade, the introduction of a new enamel for direct application on steel, which eliminates the necessity for a ground coat and permits the application of lighter coats of enamel, might result in a decline in future consumption of fluorspar for this use.

The extent of participation by the domestic industry in the postwar demand for fluorspar will depend to a large degree on the rate of duty, which has been lowered 25 percent since January 1, 1939. Between World War I and World War II, Germany, France, and England were the chief exporters of fluorspar to the United States. France is likely to have an exportable surplus after the war. Imports from England have been insignificant during the past 15 years, but as extensive development during the war has reestablished several mines it is

possible that future production may exceed home consumption. Heavy production that began with German rearming no doubt has substantially depleted the reserves in that country. Mexico, Newfoundland, and Spain, small producers before the war, will hereafter undoubtedly occupy prominent positions among the fluorspar-producing countries as a result of intensive development of deposits during the war. Inasmuch as Mexico and Spain are relatively small consumers and Newfoundland is a nonconsumer of fluorspar, future production in these countries will depend largely upon the development of export markets, probably chiefly in the United States. Therefore, it is apparent that a large, exportable surplus of fluorspar will be available in many countries after the war.

Although the wartime selling price of fluorspar will not continue after the war, the higher costs of developing and mining fluorspar at greater depths will undoubtedly prevent the price from dropping to prewar levels.

PRODUCTION AND SHIPMENTS

Production of finished fluorspar totaled 413,700 short tons in 1944, including 156,672 tons of flotation concentrates. However, this production of 413,700 tons includes 17,700 tons of finished fluorspar recovered from milling some crude ore mined before 1944. Consequently, total mine production (expressed in terms of finished fluorspar) was 396,000 tons in 1944 compared with 433,000 tons in 1943. Of the mine production in 1944, 10 mines producing over 10,000 tons each supplied 174,000 tons or 44 percent, 18 mines producing 5,000 to 10,000 tons each supplied 125,000 tons or 32 percent, 31 mines producing 1,000 to 5,000 tons each supplied 63,000 tons or 16 percent, and 23 mines producing 500 to 1,000 tons each supplied 17,000 tons or 4 percent; thus, 82 mines produced 379,000 tons or 96 percent of the total. The remainder (17,000 tons or 4 percent) of the production, in quantities ranging from a few tons to 500 tons, came from an undetermined number of small mines, prospects, waste dumps, and old workings of abandoned mines.

Fluorspar shipments from domestic mines in 1944 were the largest on record and aggregated 413,781 short tons valued at \$12,503,487, representing increases of 2 and 6 percent, respectively, over 1943, the previous peak year. Of the 1944 total, 69,536 tons were shipped by river or river-rail for delivery to consumers as compared with 49,913 tons in 1943.

Illinois (43 percent) and Kentucky (27 percent) supplied 70 percent of the fluorspar shipped in 1944 compared with 76 percent in 1943. Shipments from Illinois and Kentucky were 6 percent less than in 1943 compared with a gain of 28 percent from other producing States.

The average value of all grades of finished fluorspar shipped in 1944 was \$30.22 a short ton (\$1.15 more than the 1943 average).

The following table shows shipments of fluorspar, by States, in 1943 and 1944. (For historical table, see *Minerals Yearbook*, 1941, p. 1401.)

Shipments of fluorspar in 1944 comprised 237,108 tons of fluxing gravel and foundry lump, 153,750 tons of flotation concentrates, 21,331 tons of ground, and 1,592 tons of acid lump. The bulk of the fluxing-gravel and foundry-lump fluorspar was shipped to steel plants and iron foundries, but a comparatively small tonnage moved to plants

making cement, ferro-alloys, nickel, basic refractories, and fluxing compounds, to smelters of secondary metals, and to the Government stock pile. Hydrofluoric-acid plants took 77 percent of the flotation concentrates shipped in 1944; the remainder went to aluminum- and magnesium-reduction works, to steel, ferro-alloy, glass, and enamel plants, to smelters of secondary metals, and to the Government stock pile. About three-fourths of the ground fluorspar was shipped to glass and enamel plants; the remainder moved chiefly to manufacturers of hydrofluoric acid, welding rod, magnesium, and ferro-alloys and to smelters of secondary metals. Except for 20 tons to a steel plant, all the acid-lump fluorspar was shipped to hydrofluoric-acid plants.

The next table shows shipments of fluorspar, by grades and industries, in 1943 and 1944.

SHIPMENTS, BY USES

As is evident from the following table, the predominant purchaser of fluorspar is the steel industry, which also consumes substantial quantities of hydrofluoric acid and sodium fluoride, in which fluorspar is the basic material.

USES

As figure 1 shows graphically, the steel industry is the chief consumer of fluorspar in the United States. Fluorspar is used as a flux in basic open-hearth and basic electric steel furnaces; a comparatively small quantity is employed in Bessemer-steel furnaces. The second-largest use is in the manufacture of hydrofluoric acid, which is utilized to make artificial cryolite and aluminum fluoride (aluminum raw materials), refrigerating mediums, and insecticides; hydrofluoric acid is also used in the electrolytic refining of metals, the pickling of metals, electroplating operations, the processing of high-octane gasoline, the etching of glassware, frosting electric light bulbs, and as an aid in straw-bleaching processes, as well as for many other purposes. One of the most important wartime developments in aviation-gasoline manufacture is the anhydrous hydrofluoric acid alkylation process, in which hydrogen fluoride is the catalyst instead of the usual sulfuric acid. Another important wartime invention is the new aerosol dispenser, for protection of the Army overseas from malaria mosquitoes, in which Freon, a nonpoisonous gas employed in refrigerating systems, is used. Both developments resulted in greatly increased demand for acid-grade fluorspar in 1943 and 1944. The glass industry, which employs fluorspar as an opacifier and as a flux, ranks third in importance. The enamel industry uses fluorspar as an ingredient in frit; before the war it ranked fourth as a consumer, but because of the restrictions on the manufacture of enamel products it has been a small consumer in recent years. A new enamel for direct application on steel, which eliminates the necessity for a ground coat and permits the application of lighter coats of enamel, has recently been announced.⁵ The steel, hydrofluoric acid, and ceramic industries

Comstock, G. F., and Wainer, E., New Titanium Steel for Vitreous Enamel: Iron Age, vol. 155, No. 7, Feb. 15, 1945, pp. 60-63, 152-153.

accounted for about 95 percent of the fluorspar consumed in the United States in 1944; the remainder was used chiefly as a flux at iron foundries, magnesium-reduction, aluminum-reduction, and ferro-alloy plants and secondary nonferrous smelters, and in a formula for coating welding rods. More fluorspar was used at iron foundries, magnesium-reduction plants, and nonferrous smelters in 1944 than in 1943, but less was consumed at ferro-alloy and aluminum-reduction plants and by makers of welding rods. The use of fluorine in drinking water to prevent tooth decay continued to receive much publicity in 1944.

FIGURE 1.—Fluorspar sales (domestic and foreign) to consumers in the United States, 1942-44, by consuming industries and by sources.

SPECIFICATIONS

The chief commercial grades of fluorspar are metallurgical, ceramic, and acid. The standard chemical specification for metallurgical grade is a minimum of 85 percent calcium fluoride and a maximum of 5 percent silica and 0.3 percent sulfur; it contains 72½ percent effective calcium fluoride. Lead and zinc are also undesirable and should be held to a minimum. However, because of a scarcity of metallurgical-grade fluorspar, the Office of Price Administration, effective August 30, 1943, prohibited the sale or delivery of metallurgical-grade fluorspar containing more than 60 percent effective

calcium fluoride unless the Steel Division of the War Production Board had certified in writing to the producer that the purchaser required a higher-grade fluorspar. With the improved supply-demand position this restriction was relaxed during the latter half of 1944. The standard chemical specification for acid-grade fluorspar is a minimum of 98 percent calcium fluoride and a maximum of 1 percent silica, but a base analysis of 97½ percent calcium fluoride and 1½ percent silica was established by the Office of Price Administration on July 1, 1943. Over 0.02 percent sulfur is considered undesirable, and the moisture content should be less than 1 percent and preferably nil. As there has been no shortage in the supply of ceramic-grade fluorspar, no change was made by the Office of Price Administration in the standard specification, which is a minimum of 95 percent calcium fluoride and a maximum of 2½ percent silica.

CONSUMPTION AND CONSUMERS' STOCKS

The following tables give data on consumption and consumers' stocks of fluorspar.

Fluorspar (domestic and foreign) consumed and in stock in the United States, 1943-44, by industries, in short tons

Industry	1943			1944

Production of basic open-hearth steel and consumption and stocks of fluorspar (domestic and foreign) at basic open-hearth steel plants, 1940-44

	1940	1941	1942	1943	1944
Production of basic open-hearth steel ingots and castings..... long tons.....	55,038,000	66,056,000	67,821,000	69,695,000	71,387,000
Consumption of fluorspar in basic open-hearth steel production..... short tons.....	143,800	191,300	217,100	205,676	201,788
Consumption of fluorspar per ton of steel made..... pounds.....	5.2	5.8	6.4	5.9	5.7
Stocks of fluorspar on hand at steel plants at end of year..... short tons.....	79,800	84,200	60,400	57,200	53,100

The quantity of fluorspar used per long ton of basic open-hearth steel varies with each plant, each operator, each furnace, and each heat but probably ranges from less than 1 pound to 80 pounds. The average for all plants is 5 to 8 pounds—a relatively small proportion of the furnace charge. From 1921 (the first year for which such data

were collected) to 1940 the average consumption of fluorspar per long ton of steel made declined almost steadily from 8.2 to 5.2 pounds; it increased to 5.8 pounds in 1941 and to 6.4 pounds in 1942—the highest since 1935. However, it declined to 5.9 pounds in 1943 and 5.7 pounds in 1944. The decreased consumption in 1943 and 1944 was due chiefly to conservation measures, although some substitutes were used. Although the basic electric steel industry is a small user of fluorspar compared with the basic open-hearth steel industry, the average consumption of fluorspar (13.3 pounds in 1944) per long ton of basic electric steel made is substantially greater. Moreover, the average consumption of fluorspar per ton of basic electric steel made increased in 1944.

Fluorspar was reported consumed in 40 States and the District of Columbia in 1944, but 3 States—Illinois, Ohio, and Pennsylvania—used 239,584 tons or 58 percent of the total consumption. Illinois, the chief consuming State in 1943, was displaced by Pennsylvania in 1944. Illinois, however, maintained its rank as the largest consumer of fluorspar in hydrofluoric acid in 1944. Pennsylvania again ranked first in consumption of fluorspar in both steel and glass.

The next table shows, so far as possible without revealing the figures of individual companies, the consumption of fluorspar by States in 1943 and 1944.

PRICES

Prices fixed by the Office of Price Administration on July 1, 1943, remained in effect in 1944; they were \$30 to \$33 a short ton for metallurgical-grade fluorspar and \$37 a ton for acid and ceramic grades.

STOCKS AT MINES OR SHIPPING POINTS

According to reports of producers, the quantity of fluorspar in stock at mines or shipping points at the close of 1944 totaled 69,883 tons or 40 percent less than in 1943. These stocks comprised 19,055 tons of finished fluorspar and 50,828 tons of crude fluorspar (calculated to be equivalent to 24,000 tons of finished fluorspar).

¹ The greater part of this crude (run-of-mine) fluorspar must be beneficiated before it can be marketed.

TECHNOLOGIC DEVELOPMENTS

Results of operation of the heavy-media process by three companies in 1944 for treating fluorspar ores were apparently highly satisfactory. With this process, lower-grade ore can be mined and beneficiated than was economical with jigs, treatment costs are lowered, a better concentrate with lower tailing losses is obtained, and production is increased. During 1944 a heavy-media plant was being installed at the Mitchem mine near Keller, Ferry County, Wash., by the Western Minerals Co.; it was expected to be in operation in February 1945. The heavy-media plant of the Rosiclare Lead & Fluorspar Mining Co., which began operating in March 1944, has been described by Cronk.⁶

The Aluminum Ore Co. installed a sulfide circuit in its flotation mill at Rosiclare, Ill., during 1944. The circuit consists of a four-cell flotation machine, complete with conditioners, a filter, and a pump. It removes lead and zinc sulfides ahead of the fluorspar flotation circuit, thus resulting in low-sulfur acid-grade concentrates and a byproduct of lead and zinc sulfides. A problem of lowering the sulfur in the metallurgical-grade fluorspar concentrate of a producer in Colorado was solved by placing a Duplex Denver mineral jig, 8 by 12 inches, with a center draw-off in the mill circuit to treat the total gravel production, amounting to about 20 tons per 24 hours.⁷ The feed, ranging in size from one-fourth inch to 100-mesh, is now delivered to the jig by a dewatering screw conveyor. Fine sulfides are removed in the jig through the wedge-wire lower screen, and a small amount of coarse middlings is removed through the center draw-off openings. Formerly the concentrate recovered on jigs and tables contained 1 to 1.5 percent sulfur, pyrite, and galena, and lesser amounts of other heavy metal sulfides, but since the Denver mineral jig has been in operation the finished gravel fluorspar averages 0.6 to 0.7 percent sulfur.

The Bureau of Mines continued its metallurgical studies on fluorspar. The ore from a number of properties was investigated to determine its amenability to flotation. Further progress was made in perfecting the separation of fluorspar and barite. An investigation of various binders for agglomerating fine fluorspar for metallurgical use was conducted at the Rolla Laboratory.

⁶ Cronk, A. H., Heavy-Media Cuts Costs at a Fluorspar Mill: Eng. and Min. Jour., vol. 146, No. 1, January 1945, pp. 66-68.

⁷ Gisler, H. J., Denver Mineral Jig has Helped Fluorspar Mill Lower Sulphur Content: Mining Record (Denver), vol. 56, No. 7, Feb. 15, 1945, p. 5.

The flotation mill of Minerva Oil Co. near Cave in Rock, Ill., made its initial production in March 1944. The flotation plant of Corod Minerals Corp. near Marion, Ky., was completed but did not produce any fluorspar concentrates. The plants of A. E. Chambers near Forney, Idaho, and American Fluorspar Co. near Albuquerque, N. Mex., noted in the chapter of this series for 1943, were not completed in 1944. The flotation plant of Chaffee County Fluorspar Corp., under construction near Salida, Colo., was expected to be in operation in February 1945. Kramer Mines, Inc., whose flotation mill at Salida, Colo., was destroyed by fire on July 6, 1944, was constructing a new mill near Colorado Springs, Colo.; operation was expected to begin in February 1945. Output of flotation concentrates from domestic ore totaled 156,672 short tons in 1944 compared with 159,758 tons in 1943. However, flotation mills in the United States also recovered 4,855 tons from milling Mexican ore in 1944.

FLUORSPAR INDUSTRY IN 1944, BY STATES

Arizona.—Production in Arizona in 1944, totaling 1,044 short tons, came from mines and prospects in Greenlee, Maricopa, and Yuma Counties; that from Greenlee County was shipped to flotation plants at Deming and Lordsburg, N. Mex., and near El Paso, Tex., and the concentrating mill at Silver City, N. Mex. The concentrates recovered from the fluorspar, rather than the milling ore, have been credited in the statistics to Arizona. The fluorspar from Yuma County was a byproduct from the Sonora lead mine, and part of it was shipped to an iron foundry in California. The fluorspar from Maricopa County came from the Contact and West End Spar mines near Wickenburg, was produced by J. A. Campbell, Isaac Campbell, and A. W. Nickle, and was shipped to steel plants. During the last quarter of 1944, while endeavoring to secure milling ore for its flotation mill at Duncan, the Southwestern Mineral Co. conducted mill tests on the re-treatment of middlings from previous operations, but no commercial concentrates were produced.

California.—Production of fluorspar in California in 1944 was only 19 tons which, together with 7 tons produced in 1943, was shipped to a steel plant. It was produced at the Red Bluff mine near Midland, Riverside County, by E. T. Hermann.

In 1944 some Nevada fluorspar was ground at the plant of the Industrial Minerals & Chemical Co. at West Berkeley and shipped to magnesium-reduction plants, and some Utah fluorspar was ground at the plant of Robinson & Stephens at La Verne and shipped to a glass plant. The ground fluorspar is credited in the statistics to Nevada and Utah.

Colorado.—Reflecting greatly accelerated activity at mines in Boulder and Jackson Counties, shipments from Colorado increased to 65,209 short tons in 1944, a new record and a gain of 33 percent over 1943. The 1944 shipments comprised 39,273 tons of metallurgical-grade fluorspar and 25,936 tons of flotation concentrates.

Production of finished fluorspar in Colorado totaled 65,300 tons in 1944. However, the production includes 11,400 tons of finished fluorspar recovered from treating some crude ore mined previous to 1944. Consequently, total mine production (expressed in terms of finished fluorspar) was 53,900 tons compared with 60,500 tons in 1943.

Output came from Boulder, Chaffee, Jackson, Mineral, and Park Counties; mines in the first three supplied 87 percent of the State total.

During 1944 Harry M. Williamson & Son completed a new surface plant at its Argo mine and retimbered the shaft to the old winze level, 160 feet below the collar. At its Emmett mine the shaft was sunk 90 feet to open the seventh level, which is 556 feet below the shaft collar. Ore is now being mined by shrinkage stoping above the sixth level in the Emmett mine, 456 feet below the collar of the shaft and 374 feet below the tunnel. A caterpillar Diesel engine was installed in the power plant to add to the stand-by power for the winter when there is insufficient water to drive the waterwheel at capacity, and a new brick stack for the drier was also installed at the drying unit. Production of finished fluorspar was 63 percent greater than in 1943 and comprised 59 percent fluxing gravel and 41 percent acid-grade flotation concentrates. The ore treated in the mill came from the company-operated Argo, Brown Spar, and Emmett mines in Boulder County. Some milling ore was sold to the nearby flotation mill of the General Chemical Co.

Production of flotation concentrates at the mill (near Jamestown) of General Chemical Co. was 24 percent greater than in 1943. The output of the mill was shipped to the hydrofluoric-acid plants of the company. The flotation-mill feed comprised ore from the company-operated Alice, Burlington, Chancellor, and Yellow Girl mines in Boulder County, and some purchased ore. This company also operates a flotation mill in New Mexico.

The Colorado Fluorspar Corp., which operates a combination flotation-jig mill and a mine near Salida, Chaffee County, produced 12 percent more finished fluorspar than in 1943. Production in 1944 comprised 51 percent fluxing gravel and foundry lump and 49 percent flotation concentrates.

The flotation mill of Kramer Mines, Inc., near Salida, which started operating in October 1942, was destroyed by fire on July 6, 1944. The company had a flotation mill under construction at Colorado Springs. As a consequence of the fire, production of flotation concentrates in 1944 was 67 percent less than in 1943. The company has mines near Salida and Poncha Springs, Chaffee County, and Northgate, Jackson County; and it is reported to have acquired undeveloped reserves near its new mill in El Paso County.

The American Fluorspar Corp., operating mines near Salida and Poncha Springs (Chaffee County), produced 38 percent less fluxing-gravel fluorspar than in 1943, but its output of milling ore, which is supplied to the Fluorspar Processing Co., was 24 percent more. Considerable development was done at the Aksarben and Dostal mines. The flotation mill of the Fluorspar Processing Co.—on property of the American Fluorspar Corporation—produced 9 percent more fluorspar concentrates than in 1943. A number of improvements were made in the mill, and a laboratory was installed.

Production of fluxing-gravel fluorspar by the Western Fluorspar Corp. was $8\frac{1}{2}$ times that in 1943. The company operates a heavy-media-process plant near Northgate, Jackson County. The new plant began operating in December 1943 and replaced the mill destroyed by fire December 10, 1942. The plant feed in 1944 was divided about equally between ore from current production and ore from stock pile accumulated in 1943, when the plant was under con-

struction. The adjoining Penber fluorspar property was acquired by the Western Fluorspar Corp. in 1944. Some mine-run ore from the Penber mine was produced by M. P. Cloonan in 1944; it was shipped to a cement plant.

The Wagon Wheel Gap mine of the Colorado Fuel & Iron Corporation was operated throughout 1944 as compared with 10 months in 1943; consequently, production was 12 percent greater.

A small quantity of fluorspar was produced in 1944 by Luke E. Smith at a property near Jefferson in Park County.

Idaho.—In the course of development at the Chamac mine near Forney, Lemhi County, A. E. Chambers produced some milling ore in 1944. However, the flotation mill, noted as under construction in the chapter of this series for 1943, presumably was not completed in 1944.

Illinois.—Fluorspar production in Illinois, which reached an all-time high in 1943 after an unbroken 5-year upward trend, declined in 1944; nevertheless, Illinois maintained its rank as the chief producing State. Production of finished fluorspar was 178,600 short tons in 1944; about 98 percent came from Hardin County and 2 percent from Pope County. However, the production includes 1,600 tons of finished fluorspar recovered from treating some crude ore mined before 1944. Consequently, total mine production (expressed in terms of finished fluorspar) was 177,000 tons in 1944 compared with 204,000 tons in 1943. Much Kentucky fluorspar is milled in Illinois, and some Illinois fluorspar is milled in Kentucky; the finished fluorspar so recovered, as well as that shipped, is credited in the statistics to the State of origin. The Argo, Blue Diggings, Crystal, A. L. Davis, W. L. Davis, Dardorff, Douglas, Fairview, West Green, Hillside, Midway-North Boundary-Air Shaft, Minerva, Rose Creek, Rosiclare, and Victory properties supplied about 90 percent of the fluorspar produced in Illinois in 1944; the remainder came from many mines and prospects, including the Austin, Cave in Rock, Daisy-North Daisy, Dimick, East Green, Good Hope, Hawkins, J. W. Hill, Humm, Last Chance, Lead Hill, Lost 40, Red Tipple, Rock Candy Mountain, South Boundary-Deep Shaft, Stewart, Underwood, and Wall.

Shipments of fluorspar from Illinois (176,259 tons) were 11 percent less than the all-time record of 1943 but constituted 43 percent of the total shipped. The 1944 shipments comprised 71,516 tons to steel plants, 81,493 tons to hydrofluoric-acid plants, 14,058 tons to glass and enamel plants, 8,184 tons to iron foundries, nonferrous smelters, aluminum- and magnesium-reduction plants, and ferro-alloy, nickel, and welding-rod manufacturers, and 1,008 tons to Brazil, Canada, and Peru. Of the 1944 total, 41,790 tons were shipped by river or river-rail to consumers compared with 34,643 tons in 1943.

Although producing 18 percent less fluorspar at its flotation mill than in 1943, the Aluminum Ore Co. was again the largest producer in the United States. The mill feed comprised ore from the company-operated Argo, Blue Diggings, Fairview, Good Hope, and Last Chance mines.

In 1944, unlike 1942 and 1943, there were no strikes at the Crystal mine; as a consequence, the Crystal Fluorspar Co. produced 10 percent more fluorspar than in 1943. In 1944 the company did 14,258 feet of diamond and churn drilling, completed 501 feet of

underground development in preparing for extraction of ore, and did 356 feet of prospecting work in extension of its known ore body.

Production of gravel and flotation concentrates by Hillside Fluor Spar Mines was 9 and 5 percent, respectively, more than in 1943. The mill feed comprised ore from the Dimick, Hillside, and Wall mines at Rosiclare, Ill., and the Keystone and Guill mines near Marion, Ky., purchased ore chiefly from the Austin, Cave in Rock, Douglas, Rock Candy Mountain, and Rose Hill mines, and tailings from previous milling operations. Production and shipments of finished fluorspar from the Keystone and Guill mines have been credited in the statistics to Kentucky.

The Victory mine of the Victory Fluorspar Mining Co. produced 26 percent less fluorspar than in 1943. Production in 1944 was hampered by two local strikes.

The flotation mill of the Mahoning Mining Co. produced 10 percent more fluorspar concentrates from domestic ore than in 1943. The mill feed comprised ore from the A. L. Davis, W. L. Davis, Deardorff, East Green, and West Green mines and some purchased ore. Production of finished fluorspar comprised 77.6 percent acid-grade and 22.4 percent pelletized gravel. During 1944 the company acquired the Klondike and Mineral Ridge mines in Livingston County, Ky., where development was in progress. A comparatively small tonnage of Mexican fluorspar was also milled by the company in 1944; the flotation concentrates so recovered, as well as shipped, are not included in the statistics for Illinois.

The Minerva Oil Co., which had been developing a mine and constructing a flotation mill near Cave in Rock, brought both units into production in March 1944. However, from time to time it was necessary to make changes in the mill, and it was not operated at capacity.

The Rosiclare Lead & Fluorspar Mining Co. operated the Daisy-North Daisy, Hawkins, Midway-North Boundary-Air Shaft, Rosiclare, and South Boundary-Deep Shaft in 1944, but the Rosiclare mine was the chief producer. The ore is feed for the company heavy-media-process plant and flotation mill. Production of finished fluorspar of all grades was 11 percent greater, but shipments were 7 percent less than in 1943. Two diamond drills were operated throughout 1944 on the property of the company to find additional ore bodies and unknown veins.

The Fluorspar Products Co. operated the Lead Hill and Stewart mines and milled purchased ore from various properties. Shipments were 56 percent less than in 1943.

The Rose Creek and Douglas mines, operated by Yingling Mining Co., were worked at an increased rate in 1944. Some of the ore was milled by the company, but the bulk was sold to local mills for treatment.

Outstanding among the smaller producers in Illinois in 1944 were the Big Creek Mining Co. (Rock Candy Mountain mine); J. F. E. Austin, Keeling & Conn, and Frailey & Winters (all Austin mines); O. P. Grischy (Cave in Rock and Lead Hill mines); and the mines of the General Finance Corporation. All ore from these operations was sold to local mills.

Kentucky.—Production of fluorspar in Kentucky in 1944 continued the downward trend that began in 1942. Production of finished

fluorspar was 110,300 short tons in 1944. However, the production includes 2,400 tons of finished fluorspar recovered from milling some crude ore mined before 1944. Consequently, total mine production (expressed in terms of finished fluorspar) was 107,900 tons in 1944 compared with 119,000 tons in 1943. Shipments gained slightly, totaling 112,791 tons, but were 21 percent less than the all-time high for 1941. The 1944 shipments comprised 96,326 tons to steel plants, 11,575 tons to glass and enamel plants, 1,998 tons to hydrofluoric-acid plants, 2,797 tons to iron foundries, nonferrous smelters, and cement and miscellaneous plants, and 95 tons to Canada. Of the 1944 shipments, 27,746 tons were shipped to consumers by river or river-rail compared with 15,270 tons in 1943.

Output in Caldwell County came chiefly from the Crook, Eureka, Glass, Hollowell & Hobby, Hughett, and Senator mines.

The Hughett mine of the Hughett Mining Co., near Princeton, was nonproductive after April 11, 1944, and consequently production was 78 percent less than in 1943. Likewise, the Hollowell & Hobby mine of the New York & Kentucky Mining Co., also near Princeton, was closed in April, and output was 61 percent less than in 1943.

The Midland Minerals Corp. operated the Senator mine, near Princeton, at a greatly reduced rate in 1944.

In 1944, as in 1943, the major part of the output in Crittenden County came from a few mines—Babb, Bachelor, Big Four, Blue, Davenport, Eagle (Watson), Keystone, Pigmy, and Tabb. Most of the remainder came from many smaller mines (including the Barnes, Central, Columbia, Cook, Gillless, Green, Hickory Cane, Hodge, Krause, La Rue, Pepper Box, Reiter, Sullinger, Watkins, and Yates) and from numerous prospects; some was reclaimed from waste dumps and old workings of abandoned mines.

The Eagle Fluorspar Co. worked the Eagle (Watson) and Babb mines and produced 39 percent less finished fluorspar than in 1943. Some development was started at the Eagle mine in 1944. Perry & Loyd reworked the Eagle tailings and recovered much fluorspar.

The mill of the United States Coal & Coke Co. produced 20 percent more finished fluorspar than in 1943, but shipments increased 77 percent. The mill feed comprised ore chiefly from the company-operated Tabb mines, but some was from the Big Four mine, owned by the company but operated by Perry & Loyd.

Tonnage and dollar sales by the Kentucky Fluor Spar Co. and affiliates were 29 and 25 percent, respectively, less than those in 1943, which, however, were the largest in their history. The company operates a mill at Marion and, through its mining divisions (Roberts & Frazer and Hettiger & Frazer), operated the C. R. Babb, Carr, and Wright mines in Livingston County and the Pepper Box mine in Crittenden County. About two-thirds of the company supply came from these mines and the remainder chiefly from the Barnes, Gillless, Glass, La Rue, Nancy Hanks, and Watkins.

Production at the Keystone mine of Hillside Fluor Spar Mines was 37 percent less than in 1943. The company acquired the Guill mine in Livingston County in 1944. Although the fluorspar from these mines is finished at the company mill at Rosiclare, Ill., production and shipments are credited in the statistics to Kentucky.

At the Pigmy mine of the Pigmy Corp. (subsidiary of the Rosiclare Lead & Fluorspar Mining Co.) production was 76 percent more than

in 1943. One diamond drill was operated the entire year to find additional ore bodies and unknown veins. A 300-foot shaft, sunk years ago but from which no development had been done, was retimbered to a depth of 200 feet; it will become the main producing shaft for the Pigmy mine on the west side of the property.

Production of finished fluorspar at the Davenport mine of National Fluorspar Co. was slightly less than in 1943.

Output at the Bachelor mine of Delhi Fluorspar Corp. declined for the third successive year. However, the 1944 deficit in production was partly offset by working the Eureka mine in Caldwell County. The company also purchased both finished fluorspar and milling ore from many local producers. Nevertheless, its shipments were 37 percent less than in 1943.

Shipments of fluorspar by L. Conyer, operating the Yates mine and a mill, both near Marion, were 42 percent less than in 1943. However, most of the ore milled in 1944 was from stock and purchased from local mines, chiefly the Hughett mine.

Crider Bros. Fluorspar Co. was organized in 1944; it operated the Blue mine near Mexico, Ky., and purchased local ore. Its mine was electrified, and a new washer was added to the mill in 1944.

The Corod Minerals Corp. completed its flotation mill near Marion but made no production of fluorspar concentrates.

In Livingston County most of the fluorspar output came from the C. R. Babb, Butler, Carr, Davis, Nancy Hanks, Old Silver, Guill, and Wright mines and from reworking the C. R. Babb, Klondike, and Nancy Hanks tailings.

Output at the C. R. Babb, Carr, and Wright mines of Roberts & Frazer was 11 percent less than in 1943. E. W. Frazer reworked the tailings at the C. R. Babb mine and recovered 536 tons of fluorspar.

Production at the Nancy Hanks mine, operated by W. V. Haynes, Jr., and Tinsley & Loyd, was slightly less than in 1943. In addition, Tinsley & Loyd reclaimed a substantial tonnage of sand spar from Nancy Hanks tailings.

Butler & Moodie (reclaiming fluorspar from Klondike tailings) and Butler, Moodie & Craighead (operating the Old Silver mine, which was opened in 1944) made substantial outputs during the year.

In the Central Kentucky district production of fluorspar declined to 1,867 tons (2,469 tons in 1943). Output from this district in 1944 came from the Faircloth mine in Woodford County near Wilmore, operated by Ralph E. Jones until August when it was sold to the Lone Oak Ore Co.; the Lone Oak mine near Harrodsburg in Mercer County, operated by the Lone Oak Ore Co. until September 10 when it was sold to J. B. Towles; the Gobel Dean mine near Talmage in Mercer County, operated by Mercer Minerals, Inc.; and the Twin Chimney mine near Mundys Landing in Mercer County, operated by the Lone Oak Ore Co. until March when it was sold to Ollie Neal who sold it on December 28 to Albert Brauer & Co. The last-named company is opening the Britain mine, also near Mundys Landing.

Nevada.—Shipments of fluorspar from Nevada in 1944 (7,293 short tons) were 16 percent smaller than in 1943 and 19 percent under the all-time record of 1941. Most of the 1944 total went to steel plants, but some was shipped to hydrofluoric-acid and cement plants and to nonferrous smelters.

The chief producing mine in Nevada in 1944 was the Baxter in Mineral County, operated by V. S. Baxter; its production was 8 percent less than in 1943. The other producing mine was the Daisy in Nye County, operated by J. Irving Crowell, Jr., and its production was 36 percent less than in 1943.

New Mexico.—Production of fluorspar in New Mexico continued its upward trend, uninterrupted for the eighth successive year. Production of finished fluorspar totaled 42,800 short tons, a gain of 15 percent over 1943. However, the 1944 production includes 2,300 tons of finished fluorspar recovered from treating some crude ore mined before 1944. Consequently, total mine production (expressed in terms of finished fluorspar) was 40,500 tons compared with 37,700 tons in 1943. The output came from Catron, Dona Ana, Grant, Hidalgo, Luna, and Valencia Counties.

Shipments from New Mexico totaled 42,973 tons, a gain of 16 percent over the former all-time high of 1943. The 1944 shipments comprised 22,557 tons of flotation concentrates and 20,416 tons of metallurgical-grade fluorspar.

The flotation mill of the General Chemical Co. at Deming was not operated during July and August; consequently, production was 17 percent less than in 1943. The mill feed comprised ore from the company Spar Group and Sadler mines in Luna County and the Osmer mine in Grant County and purchased ore from local mines. Virtually all the flotation concentrates produced were shipped to the hydrofluoric-acid plants of the company.

The flotation plant of the Zúñi Milling Co. at Los Lunas, which began operating in March 1943, was in 1944 again the largest producer of flotation concentrates in New Mexico. Production from both domestic and Mexican ore was 11 percent greater than in 1943. The mill feed comprised ore chiefly from the company mines in Valencia County, but some was purchased from local producers and from Mexico. However, the concentrates recovered from milling Mexican ore, as well as shipped, are not included in the statistics for New Mexico. The fluorspar deposits in the Zúñi Mountains have been discussed by Kutnewsky.⁸

The Grattan flotation mill at Deming was acquired on August 1 by Edgar J. Marston, who operated it the remainder of the year. In the plant a 5½- by 5-foot ball mill and new loading and unloading facilities were installed, the drying unit was enlarged and improved, and the flotation cells were improved. The mill feed comprised ore from the Fourth of July and Poor Boy mines in Greenlee County, Ariz., the Greenleaf and Sadler mines in Luna County, and the Mohawk mine in Grant County—all operated by Marston—and ore purchased from local mines, chiefly the Burro Chief in Grant County. The concentrates produced were shipped chiefly to hydrofluoric-acid plants.

The heavy-media-process plant at Gila, owned by the Metals Reserve Co. and operated for that company by the International Minerals & Chemical Co., was active throughout 1944 and produced 17,530 tons of fluxing-gravel fluorspar, which was placed in the Government stock pile at Gila. The plant feed comprised ore supplied chiefly by the Brown-Johnson Corporation from the Clum mine near Gila, by H. E. McCray from the Burro Chief mine near Tyrone, by

⁸ Kutnewsky, Fremont, Fluorspar Deposits in the Zúñi Mountains: *Mining Jour.* (Phoenix, Ariz.), vol. 28, No. 11, Oct. 30, 1944, pp. 4-5.

the Glenwood Mining & Milling Co. from the Huckleberry mine near Glenwood, and by D. F. McCabe from the Great Eagle mine near Red Rock. The plant has been described in the *Mining World*.⁹

The American Fluorspar Co. carried on development at the Blackbird prospect near Albuquerque in Bernalillo County and continued construction of a flotation mill.

Texas.—Production of finished fluorspar in Texas increased to 4,906 short tons (a new record) in 1944 from 1,253 tons in 1943. Shipments likewise jumped to 4,769 tons (960 tons in 1943). Production came chiefly from the Eagle Mountains mine in Hudspeth County near Van Horn, operated by the Western Fluorite Co., which completed a mill on January 15, 1945. The Eagle Mountains deposits have been described by Needham.¹⁰

The flotation mill of Alloy Metals near El Paso, Tex., began producing fluorspar concentrates in June. The mill feed comprised ore from mines in Arizona, New Mexico, and Texas and in Mexico. The mill was sold on October 19 to the Continental Milling Co., which operated it during the remainder of the year and milled ore from the Moll mine in Mexico. The flotation concentrates recovered from milling Mexican ore, as well as shipped, are not included in the statistics for Texas.

Utah.—An important event in Utah in 1944 was the beginning of operations in June at the new concentrating mill of the Tintic Standard Mining Co. near Milford. The mill feed came chiefly from its newly developed Cougar mine in Beaver County, but some purchased ore was also milled. The mill has been described briefly in the *Mining and Contracting Review*.¹¹ Mainly as a result of this operation, production of finished fluorspar in Utah increased to 3,490 short tons in 1944, an all-time high. Contributing also to the production were: Fred Staats, operating the Staats mine; the Western Fluorite Co., operating mines near Milford; the Manassa Mining & Milling Co., operating the J. B., Brown Thrush, and Manassa mines; and H. J. Holt, operating the Blue Bell mine—all in Beaver County; and George Spor & Sons, operating the "Spor" mine in Juab County. The Western Fluorite Co. and the Manassa Mining & Milling Co., both of which use the mill of the former, are considering addition of a flotation unit in the mill.

Washington.—There was no production of finished fluorspar in Washington in 1944. However, development was under way at the Mitchem mine in Ferry County near Keller by the Western Minerals Co., which virtually completed a heavy-media-process plant for treating the ore.

Wyoming.—The first commercial production of fluorspar in Wyoming was reported made in 1944; it amounted to 19 short tons of high-grade gravel and was mined from a pocket in one of the feldspar deposits of the Wyoming Feldspar Co. in Albany County near Federal. The pocket was exhausted.

FOREIGN TRADE

Imports.—Receipts of imported fluorspar into the United States established a new record of 92,499 short tons in 1944, a gain of 112

⁹ *Mining World*, International Minerals & Chemical Corp. Employs Coarse Concentration to Produce Metallurgical Grade Fluorspar: Vol. 6, No. 6, June 1944, pp. 26-29.

percent over 1943 and 22 percent more than in 1926, the previous record year. Some of the imported fluorspar received in 1944 was placed in bonded warehouses.

Fluorspar imported for consumption in the United States was 87,200 tons, a gain of 99 percent over 1943. The imports in 1944 comprised 5,562 tons containing more than 97 percent calcium fluoride and 81,638 tons of lower grade. They were valued¹² at \$1,680,104. The value assigned to the higher-grade foreign fluorspar averaged \$27.59 a ton in 1944 and that of the lower-grade \$18.70. The cost to consumers in the United States also includes duty, loading charges, insurance, consular fee, and freight to consuming plants. The duty on fluorspar containing not more than 97 percent calcium fluoride is \$5.625 a short ton and on fluorspar containing more than 97 percent calcium fluoride \$3.75 a ton.

¹ For historical table, see Minerals Yearbook, 1941, p. 1401.

¹² As defined in sec. 402 of the tariff act of 1930, "The value of imported merchandise * * * is the foreign value or the export value, whichever is higher—that is, the market value or the price at which the merchandise, at the time of exportation to the United States, is offered for sale in the principal markets of the country from which exported, including the cost of containers or coverings and all expenses (including any export tax) incident to placing the merchandise in condition ready for shipment to the United States."

In 1944, as in 1943, the bulk of the imported fluorspar was delivered to Government stock piles. However, 6,487 tons of the imports in 1943 and 1944 were milled in 1944 at flotation plants in the United States; and 4,494 tons of acid-grade, 229 tons of ceramic-grade, and 132 tons of metallurgical-grade fluorspar were recovered therefrom.

The following table, compiled from data furnished to the Bureau of Mines by importers and by domestic companies milling foreign fluorspar, shows the quantities of imported fluorspar delivered to consumers in the United States in 1943 and 1944, irrespective of year of importation into the United States; it differs from the preceding table, which shows the quantity and grade imported into the United States during 1943 and 1944. The quantities in the following table are based upon the actual outturn weights and include the finished fluorspar recovered from milling foreign ore rather than the ore milled.

Imported fluorspar delivered to consumers in the United States, 1943-44, by uses

Use	1943			1944

¹ Estimated.

Exports.—Producers of fluorspar reported exports of 1,980 short tons of fluorspar valued at \$65,909 in 1944 compared with 9,044 tons valued at \$246,973 in 1943. The exports by producers in 1944 comprised 55 tons of fluxing gravel, 440 tons of ceramic ground, and 866 tons of flotation concentrates to Canada; 600 tons of flotation concentrates to Peru; and 8 tons of ceramic ground and 11 tons of flotation concentrates to Brazil.

Fluorspar reported by producers as exported from the United States, 1940-44

WORLD PRODUCTION

The following table shows world production of fluorspar by countries from 1937 to 1944, insofar as statistics are available. Because of restriction on the publication of statistics by the governments of many countries, few figures are available since 1939.

World production of fluorspar, 1937-44, by countries, in metric tons¹

[Compiled by B. B. Waldbauer]

¹ In addition to countries listed China produces fluorspar, but data of output are not available.² Data not available.³ Exports.⁴ Estimate.⁵ January to June, inclusive.⁶ Estimate included in total.

Canada.—According to the Dominion Bureau of Mines, production of fluorspar in Canada was 5,748 metric tons¹³ (5,730 tons from Ontario and 18 tons from Quebec) in 1944 compared with 10,169 tons in 1943. In Canada output falls far short of consumption, and the greater part of the deficiency is met by importations from Mexico, Newfoundland, and the United States. Imports in 1943 were 70,248 metric tons.

Great Britain.—Following the outbreak of war in 1939 Great Britain's greatly expanding war industries created an increased demand for fluorspar, chiefly by steel and hydrofluoric-acid manufacturers. Before the war the industry was in a chaotic and unprofitable condition, and most of the production, particularly in Derbyshire, was from dumps of fluorspar-gangue rejects of old lead mines, but such sources of supply were limited. Moreover, as the richest dumps had previously been worked the reserves had been much depleted, and the fluorspar remaining was of poor quality. Because the output from the waste dumps was insufficient to meet the increased wartime demand and to insure the maintenance of future supplies, the appeal of the Ministry of Supply to increase production and to develop underground deposits that were known to exist met with a most encouraging response, and as a consequence several mines were opened and equipment for beneficiating the material in waste dumps was installed. Moreover, in order that production and supply

¹³ 1 metric ton is equivalent to 1.10231 short tons.

problems might be dealt with in the most efficient manner, the British Fluorspar Producers' Association was formed. Production of fluorspar in the United Kingdom averaged 31,373 metric tons during the 10 years 1929-38; since that time it has increased almost progressively and reached 55,106 metric tons in 1943.

Mexico.—As a result of intensive development in Mexico in recent years, many deposits have been opened and that country, formerly a small producer, has now become an important one. Reserves are said to be large. Exports were 56,450 metric tons in 1944 (22,469 tons in 1943). The bulk of the exports went to the United States, but some went to Canada. During 1944 the Continental Milling Co. acquired the flotation mill of Alloy Metals near El Paso, Tex., for milling ore from the Moll mine.

Newfoundland.—Before 1942 the St. Lawrence Corp. of Newfoundland, Ltd., was the only producer of fluorspar in Newfoundland, and between 1933 (when the first shipments were made) and 1941 output ranged from 1,451 to 14,697 metric tons. During 1942 production was inaugurated at the newly opened mine of Newfoundland Fluorspar, Ltd., a subsidiary of the Aluminum Co. of Canada, Ltd.; as a consequence, output of fluorspar in Newfoundland skyrocketed to 66,170 tons in 1943 but declined to 58,290 tons in 1944. Exports were only 42,016 metric tons in 1944. The St. Lawrence Corp. of Newfoundland, Ltd., has a gravity-concentration mill and a flotation mill for treating the ore from its mines; the finished fluorspar is shipped to Nova Scotia and the United States. Newfoundland Fluorspar, Ltd., ships its crushed fluorspar to Arvida, Quebec, where it is treated by flotation; the resultant acid-grade concentrate is used by the Aluminum Co. of Canada, Ltd.

Fluorspar reserves of Newfoundland are reported to be large. According to Van Alstine:¹⁴

Shafts have been sunk and underground work has been done on 7 veins, but nearly all of the present production is from 4 veins. Some veins are more than a mile long and contain numerous workable lenses. Mining has progressed to a maximum depth of 350 feet, and no vein has been mined to the lower limit of workable fluorspar. Veins are of two types: High-grade containing over 95 percent CaF_2 and averaging about 5 feet thick, and lower grade containing about 75 percent CaF_2 and averaging between 15 and 20 feet thick. No marked changes in the mineralogy or grade of the fluorspar veins have been observed with increased depth of mining to a level of 350 feet.

Spain.—Chiefly as a result of demand by Germany and the United States, production of fluorspar in Spain, formerly a relatively small producer, has increased phenomenally since 1941. During the 5 years 1936-40 production averaged 7,509 metric tons annually; it increased to 15,400 and 16,297 tons, respectively, in 1941 and 1942 but jumped to 35,911 and 51,022 tons, respectively, in 1943 and 1944. The bulk of the output comes from Oviedo Province and is produced at the Berbes, Caravia, Collada, Dosal, and Pilar mines. A flotation mill was reported to have been installed at Pinzales, Gijón Province, to treat ore from the Collada mine. Other producing mines are the Papiol in Barcelona Province, the Osor in Gerona Province, and the Fuenteovejuna in Córdoba Province. Control of the Papiol, Osor, Collada, and Caravia mines was obtained by German companies in 1943.

¹⁴ Van Alstine, R. E., Fluorspar Deposits of St. Lawrence, Newfoundland: Econ. Geol., vol. 39, No. March-April 1944, pp. 109-132.

CRYOLITE

Imports of cryolite were 15,680 long tons valued at \$1,155,787 in 1944 compared with 46,400 tons valued at \$3,117,888 in 1943. Except for a few hundred pounds from Canada in 1944, the cryolite imported in both years came from Greenland.

Cryolite occurs in commercial quantity and is mined at only one place—Ivigutut, Greenland. Gibbs¹⁵ has described the mine at Ivigutut, the grades of ore produced, methods of processing and purification, and various uses of cryolite.

Artificial cryolite was manufactured in the United States in 1944 by the Aluminum Ore Co. at East St. Louis, Ill. Production was 78 percent less than in 1943. As a measure of insurance for the war program, plants for the manufacture of artificial cryolite were completed in 1943 at Bauxite, Ark., by the Aluminum Ore Co., and at Cornwells Heights, Pa., by the Pennsylvania Salt Manufacturing Co., but neither has been operated.

The chief use of cryolite is in the reduction of aluminum; comparatively small amounts are used in glass, enamels, abrasives, and insecticides.

A sizeable proportion of the cryolite used in the United States is made from fluorspar. According to Frary:¹⁶

The fluorspar is treated with sulfuric acid to produce hydrofluoric acid, and this is neutralized with the proper amounts of soda ash and aluminum hydrate to produce the cryolite, which is a double fluoride of sodium and aluminum (Na_3AlF_6). The artificial cryolite is quite satisfactory and, in fact, considerably lower in objectionable impurities than the natural cryolite usually used. There would be no serious difficulty in getting along with the artificial product if the supply of natural cryolite from Greenland is shut off.

Because of a large reserve of cryolite in the United States and cut-backs in aluminum production, all restrictions on its use were removed on October 6, 1944, by the War Production Board through revocation of Preference Order M-198, which had been issued on September 18, 1942.

SUMMARY

Stimulated by the active market for glass and glass products and a heavy demand from the armed forces for chinaware, dinnerware, and sanitary pottery and despite labor shortages the outputs of both crude and ground feldspar in 1944 increased compared with 1943. In tonnage, each was only 3 percent under the record year 1941. Total realization for crude spar sold in 1944 was the highest on record, 10 percent above 1943, the previous high. The total value of ground feldspar in 1944 also established a new record and was 2 percent over 1941, the former peak year in realization for ground spar. Production of crude feldspar in North Carolina in 1944, aided to some extent by the active hunt for mica, surpassed by 10 percent its largest previous output (in 1943).

¹ Figures on imports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

The increased activity in the feldspar market in 1944 compares favorably with a 7-percent over-all increase in the value of glass products.² Glass container production was 7 percent higher than in 1943 and shipments about 1½ percent greater, with an accompanying jump of 15 percent in inventories at the end of 1944. Plate-glass production in 1944, although considerably below prewar levels, increased 36 percent compared with 1943. Of particular interest is the demand created by the commissioning of many ships and the supplying and outfitting of the many new naval and military establishments, which caused a large gain in, and to a more limited extent, a continuing market for chinaware, semivitrified dinnerware, and sanitary and electrical porcelain.

POSTWAR OUTLOOK

The prosperity of the feldspar industry is intimately associated with fluctuations in glass, pottery, and enamel manufacture because over 95 percent of the ground feldspar marketed in the United States is generally consumed by the ceramic industries and over half in the manufacture of glass alone. Any factor, therefore, which influences these industries inevitably in turn affects the production of feldspar.

Two major movements, it is believed, will affect profoundly the fortunes of the feldspar operators: First, construction activity—the prevalence of new building, particularly residential construction, and, to a considerable extent, also the accumulated need for extensive modernization of existing housing, especially kitchen and bathroom renovation; and second, the increasing trend toward the use of more glass in all realms of domestic and industrial economy.

Increased residential and commercial building will bring about a greatly expanded market for floor and wall tile and for porcelain enameled products as the current output of both of these industries has been curtailed on account of war priorities. In the manufacture of these products, 10 to 55 percent and 25 to 50 percent, respectively, of the batch ordinarily consist of feldspar, and detailed and extensive plans for expansion in the postwar markets have been projected. Demand for electrical and sanitary porcelain, as well as whiteware and hotel china, undoubtedly will improve when building activity gets under way.

Structural glass—glass brick, hollow tile, glass walls, partitions, and similar materials—has been the subject of much investigation and will share in postwar construction plans. In this connection, the so-called “solar” heating, with the greater glassed area and thicker, larger individual glass pieces, is a new and interesting development. Coal and other chutes of abrasion- and acid-resistant glass have proved feasible in certain instances. Glass containers, a heavy consumer of feldspar, have excellent prospects of retaining some part, at least, of the business taken over on account of shortages of tin and steel. Because of shortages and tight supplies of materials such as plastics steel, nickel, copper, aluminum, zinc, and rubber in recent war years glass has been used as a replacement in many industrial applications. Also of considerable interest to the marketer of feldspar is the expanding development of glass fiber, glass wool, and the more recently developed combinations of glass fibers with other substances such as asbestos and plastics.

² Glass Industry, vol. 26, No. 3, March 1945, p. 134.

In view of probable expansion in the feldspar market and exhaustion of many of the more readily available deposits of the better grades of spar, the beneficiation of low-grade feldspars or intimately mixed material has attracted the imagination of many of the industry's key men. Now for several years a certain amount of run-of-mine spar has been processed by fine grinding and removal of impurities either by screening or air separation, followed by magnetic separation. The application of flotation methods to the refining of feldspar, however, is a new and promising development. A plant recently has been placed in operation in North Carolina to treat alaskite rock, a quartz-feldspar pegmatite occurring in abundance in the Spruce Pine area in that State. The widespread distribution of feldspar in rock of a type similar to alaskite, such as granite, points to an almost unlimited reserve, which with the development and perfection of flotation separation would become presently available. The more general application of flotation presages also a radical change in mining methods—the ultimate substitution, in large part, of large-scale quarrying for the hand operation of many comparatively small, isolated pits.

DOMESTIC PRODUCTION

Larger outputs in response to a greatly augmented demand, particularly from glass manufacturers and potteries, were hampered by labor shortages, due in a large degree to competitive war industries and to selective service calls for available manpower; increased costs; and tightness of supply of new equipment and replacements.

Following the usual practice in the industry, crude feldspar is reported in long tons of 2,240 pounds and ground feldspar in short (net) tons of 2,000 pounds.

Crude feldspar.—The active demands for crude feldspar in 1944 resulted in an increase of 6 percent in quantity compared with 1943. The tonnage sold or used was only 3 percent less than in the record year 1941. The value of the crude spar sold in 1944 reached a new high and was 10 percent above that reported in the highest previous year (1943).

Crude feldspar sold or used by producers in the United States, 1940-44

[Value at mine or nearest shipping point]

1942.....	316,166	1,546,702	4.89				

No clear picture of increase (or decrease) of production by producing sections or regional areas emerges from a study of the changes of output in 1944 in individual States or combination of States, except perhaps for the North Carolina-Virginia producing area, where production increased considerably. In New England and in the West, some States were higher and some lower than in 1943.

Feldspar was mined in the same 13 States in 1944 as in 1943 and 1942. In 1944 sales in North Carolina, the largest producer, totaled

122,857 long tons valued at \$778,007, a new record in both quantity and value—10 and 19 percent, respectively, larger in tonnage and value than in 1943. Production in Maine and Virginia increased 19 and 17 percent, respectively. Tonnages mined in New Hampshire and Arizona also were substantially higher than in 1943, although actual data or approximate percentages of change may not be shown. Output in Wyoming was the largest ever produced in that State. On the other hand, California, Colorado, Connecticut, New York, and South Dakota reported small to sizable declines in output.

¹ Included under "Undistributed."

² Includes States indicated by "(1)."

Quotations on crude feldspar are not reported in trade publications dealing with mineral industries. However, average realizations have been computed from the production questionnaires returned to the Bureau of Mines each year by the operators. According to these data, the average sales realization per long ton for crude feldspar in 1944 increased 4 percent to \$5.54 compared with \$5.34 in 1943. The 1944 figure was the highest reported since 1931. Average realizations for most States were higher in 1944 than in 1943. Small decreases appear in four States only—California, Maine, New Hampshire, and South Dakota. Averages per ton for certain States in 1943 and 1944 (1943 in parentheses) follow: North Carolina \$6.33 (\$5.85); Virginia, \$6.13 (\$5.98); Connecticut, \$6.62 (\$6.58); Maine, \$5.98 (\$6.17); Colorado \$5.19 (\$4.29); South Dakota, \$4.45 (\$4.83).

Ground feldspar.—Sales of ground feldspar by merchant mills in 1944 increased 2 percent in quantity and 8 percent in value compared with 1943 and were only 3 percent less in quantity than in the record year 1941. Total value of sales in 1944 established a new high—\$3,863,026 or 2 percent greater than in 1941, the former peak year. North Carolina and Tennessee plants combined furnished 32 percent of the total ground feldspar sold compared with 30 percent in 1943 and 26 percent in 1942. In most States relative production changed very little in 1944 compared with 1943. Sales of feldspar of Canadian origin ground in merchant mills in the United States in 1944 totaled only 2 percent of the total merchant sales, as in 1943, compared with

3 percent in 1942 and 6 percent in 1937. In addition to the tonnage just indicated, relatively small tonnages of Canadian origin are ground by consumers, principally pottery and cleanser manufacturers, who import this product direct and whose data are not included in these compilations.

Ground feldspar sold by merchant mills ¹ in the United States, 1940-44

¹ Excludes potters or others who grind for consumption in their own plants.

South Dakota in 1944, as in 1942 and 1943, ranked first in production of ground feldspar, followed by Tennessee, North Carolina, Colorado, and New Hampshire. Of those States for which figures may be shown, New Jersey-Connecticut in 1944 increased 6 percent and North Carolina-Tennessee increased 10 percent compared with 1943. Arizona and Colorado both showed considerable gain in production in 1944, but shipments from South Dakota and Virginia declined.

The average realization per short ton for ground feldspar in 1944 rose to \$11.26, an increase of 5 percent compared with 1943, and was the highest realization since 1938 (\$11.50). In all States except Arizona, California, and Illinois, the average value of ground spar increased, the percentages of change varying in most States from less

than 1 to about 5. Realization in Arizona and California in 1944 was less than in 1943, but in Illinois it remained unchanged. Average values per short ton for individual States in 1944 ranged from \$7.03 to \$18.56. Average realizations for selected States in 1944 follow: Colorado, \$7.03; South Dakota, \$7.96; North Carolina-Tennessee, \$12.03; New Hampshire, \$11.26; Maine, \$15.92; and New Jersey-Connecticut, \$18.56.

According to E&MJ Metal and Mineral Markets, quoted prices of ground feldspar in 1944 remained unchanged compared with those reported in the last two or three years. Potash and soda feldspars, f. o. b. North Carolina, 200-mesh, white, in bulk, were quoted at \$17 and \$19 per short ton, respectively. Maine potash and soda feldspars carried similar quotations. Granular glass feldspar, f. o. b. North Carolina, 20-mesh, white, in bulk, was quoted at \$12.50 per ton, and semigranular glass spar at \$11.75 per ton. Quotations on Virginia feldspar, as listed by the same source, were: No. 1, 230-mesh \$18; 200-mesh, \$17; glassmakers' spar No. 18, \$12.50; and No. 17, \$11.75. Ground feldspar for enamelers' use, ranged from \$14 to \$16 per ton, f. o. b. on either a Spruce Pine (N. C.), or Keene (N. H.) basis.

CONSUMPTION AND USES

Crude feldspar.—Most crude feldspar is sold to merchant mills, which may obtain their requirements from several mines or localities. The raw spar is stock-piled, sorted according to grade and source, blended and ground to specified fineness, perhaps run through magnetic separators to remove excess iron, and sold to ultimate consumers. However, a few pottery and enamel manufacturers purchase part or all of their feldspar crude and grind it in their own mills. Certain makers of soap, cleansers, and sweeping compounds also mine or purchase crude feldspar, largely from New England, Virginia, and North Carolina, and after grinding or otherwise processing it utilize the abrasive properties of the spar in their products. Manufacturers of artificial teeth annually consume a small tonnage of very carefully selected crude material, which must be free of all grit and is sold at a considerable premium over the No. 1 grade commercial feldspar.

Ground feldspar.—Sales of ground feldspar to ceramic industries in 1944 were 98 percent of total shipments; as a rule they constitute annually more than 95 percent of such shipments. Most of the ground spar consumed is used by glass and pottery makers. Shipments to the glass trade in 1944 totaled 220,734 short tons, a new high for this industry and about 3 percent above 1943 sales, although representing about the same proportion of total sales as in 1943 (64 percent). Sales to potteries increased to 31 percent of the ground spar sold. Percentages of total value of sales in 1944 for these two uses were: Glass 51 percent and pottery 43 percent. Sales of enamel remained at low ebb, although slightly above 1943. Sales of ground spar in 1944 for use in soaps, cleansers, and abrasives were somewhat less than in 1943. The remainder of the ground feldspar sold by merchant mills in 1944 (much less than 1 percent of total shipments) was utilized for miscellaneous ceramic purposes other than glass, pottery, or enamel and in various other applications, largely not specified.

Ground feldspar sold by merchant mills in the United States, 1942-44, by uses

Use	1942		1943		1944

Distribution of shipments of ground feldspar from merchant mills into consuming States in 1944 showed little change, except for shipments into Pennsylvania, which increased 32 percent, and into California, Mississippi, New York, and Texas, which showed increases of less magnitude. Shipments to most other important consuming States in 1944 were slightly lower than in 1943. Shipments in 1944 to Illinois and Pennsylvania each comprised 14 percent of the total shipments; to West Virginia, 13 percent; to Ohio and Indiana, 12 percent each; to New Jersey, 11 percent; and to New York, 6 percent. Sizable shipments also were made to Maryland, Oklahoma, Tennessee, Texas, and Wisconsin.

¹ Included under "Other destinations"; separate figure for State not available.

² Includes Arkansas, Colorado, Connecticut, District of Columbia, Hawaii, Kentucky, Louisiana, Maryland (1940-41), Massachusetts (1940-41), Michigan, Minnesota, Mississippi, Missouri, Oklahoma (1940-41, 1943-44), Puerto Rico, South Carolina, and Texas, and other States (shipments to which cannot be segregated); also small shipments to Canada, England, and Mexico.

TECHNOLOGIC DEVELOPMENTS

Of particular interest in the development of glass and its products—and for this reason to the feldspar industry whose chief market is the glass trade—are the increase in container manufacture, the greater demand for various glass-fiber goods, and the more widespread use of heat-resisting kitchenware and tableware. In this connection may be mentioned particularly the use of glass fibers combined with other

substances to create new products with improved characteristics. A textile of glass and asbestos, for instance, that combines high strength with light weight and is exceedingly resistant to abrasion, high temperatures, and corrosive fumes, has been developed by Owens-Corning Fiberglas Corp.³ Another new application is the mixture of glass fiber with plastics,⁴ which opens a whole field of new products of unexplored characteristics and latent usefulness.

Laboratory and plant-trial studies of the use of soda feldspar as a complete replacement of the usual potash feldspar in whiteware bodies were reported by Blackburn and Loomis.⁵ Difficulty of maintaining uniformity of the feldspar constituent in the mixtures used in the manufacture of pyrometric cones was described in a study of their constitution.⁶

The use of glass of controlled solubility has been suggested as a fertilizer.⁷ All of the elements necessary for plant growth except nitrogen, water, and organic material, may be included in the glass structure. Experiments were carried out on fused mixtures of rock phosphates, potassium carbonates, and silica. Feldspar, however, might be used as a source of potash, and other rocks as sources of various mineral raw materials, on the theory that when crystalline substances are heated sufficiently to form a glass, their lattice structure is broken down and the constituent mineral matter becomes more readily assimilable as plant food.

The manufacture of refractory articles, using a powdered nonplastic material (not an oxide) such as SiC , B_4C , BN , feldspar, singly or as mixtures, is described in a recent British patent.⁸ The material is plasticized by mixing with a metal stearate or other fatty or aromatic acid salt in a suspension of a volatile organic liquid, such as turpentine, and is dried and granulated through 40-mesh screen. The product may be shaped by pressing, extrusion, throwing on a potters' wheel, or other suitable means. Finely divided feldspar has been used as the abrasive element in the preparation of a liquid abrasive polishing composition intended for smoothing and brightening lacquered and enameled surfaces.⁹

OTHER DEVELOPMENTS

After preliminary tests, including pilot-plant operation at Erwin, Tenn., which had proved it possible to recover a clean feldspar low in free silica from alaskite rock, a quartz-feldspar pegmatite abundant in that section of the State, the Consolidated Feldspar Corp. has erected a full-scale flotation plant at Kona, N. C., to treat this comparatively low-grade material. The mill, planned eventually to have a capacity of 750 tons, also will recover quartz and mica as byproducts.¹⁰ Cold River Minerals, Inc., Bellows Falls, Vt., leased the mine and mill of

the General Minerals Corp. Work started in July 1944 and continued until the early part of February 1945, when the mill was destroyed by fire. Plans are being considered to rebuild. The Atlas Feldspar Corp., Broadalbin, N. Y., has been liquidated. A new feldspar grinder in California is Robinson & Stephens, at La Verne.

NEPHELINE SYENITE

The production and use of nepheline syenite, particularly in the manufacture of glass, continued to provide lively competition for feldspar, although output decreased slightly. A broad program of research has widened the practicable applications of nepheline to other branches of ceramics, such as pottery, sanitary and electrical porcelain, floor and wall tile, and other related uses. In the field of raw leadless glazes for whiteware, it is also claimed that nepheline syenite promotes early vitrification and that its use is preferable to that of feldspar.¹¹ The principal market, however, remains the manufacture of glass and glass products.

Nepheline syenite is not produced commercially in the United States. Except for Russia, the volume of whose output is not known, Canada is the only known producer. The American Nepheline Corp. has operated a quarry at Blue Mountain, Methuen Township, Peterborough County, Ontario, since 1936. A processing mill was erected at Lakefield, Ont., in that year. Most of the quarry's production, however, now is shipped to the larger, more recently erected mill at Rochester, N. Y., which supplies both glass and pottery grades as well as small amounts for the enameling trade. After preliminary flotation tests by the Canadian Bureau of Mines, investigation on a semi-commercial scale was undertaken during 1943 at the Rochester plant. A combination of jigging and flotation proved effective in eliminating the major part of the most objectionable impurity, corundum, and the entire Rochester mill was converted to flotation the following year (1944).

Port Coldwell Mines & Metals, Ltd., which in 1943 acquired the nepheline property of the former Port Coldwell Mining Syndicate at Port Coldwell, on the northern shore of Lake Superior, obtained control of nepheline syenite deposits near Bancroft, Hastings County, Ontario. This firm has extensive plans for erecting a new 100-ton mill in this area. The Port Coldwell deposits apparently remain unexploited.

Known occurrences of nepheline syenite in Canada, other than those mentioned above, are in the French River area, Georgian Bay district, Ontario; in the Montreal and Labelle-Annonciation areas in Quebec; and in the Ice River district, near Field, in British Columbia.¹² A deposit of nepheline syenite recently has been reported near Wausau, Wis.¹³

As already indicated, the larger part of the Canadian output is shipped to Rochester, N. Y., to be ground and marketed in the United States. No receipts of Canadian ground material were reported in 1944. Imports of crude nepheline syenite in 1944 decreased 9 percent

¹¹ Swift, Howard R., and Harmon, C. G., Raw Leadless Whiteware Glazes: Jour. Am. Ceram. Soc., vol. 28, No. 2, Feb. 1, 1945, pp. 48-52.

in quantity and value compared with the peak year 1943, although they were substantially higher than in 1942. All imports of crude and ground nepheline into this country have originated in Canada.

Nepheline syenite imported for consumption in the United States, 1940-44

Year	Crude		Ground		Year	Crude		Ground	
	Short tons	Value	Short tons	Value		Short tons	Value	Short tons	Value
1940.....	27, 888	\$87, 162	6	\$25	1943.....	43, 105	\$150, 225	737	\$7, 690
1941.....	35, 799	112, 101	1, 359	13, 695	1944.....	39, 043	136, 664	-----	-----
1942.....	36, 990	120, 688	4	44					

Quotations on crude nepheline syenite do not appear in the trade press. However, average values per short ton (estimated foreign market value) of imports of this product into the United States in recent years were as follows: 1940 and 1941, \$3.13; 1942, \$3.35; 1943, \$3.49, and 1944, \$3.50. Canadian Chemistry and Process Industries reported quotations during 1944 on prepared (ground) nepheline syenite at the same levels as in 1942 and 1943: Grade A, 20-mesh, bulk, in carlots, \$11.75 per ton; grade A, 200-mesh, bulk, in carlots, \$16.50 per ton; and grade B, dust, bulk, in carlots, \$10 per ton, f. o. b. Lakefield, Ontario. However, most of the 200-mesh material now is ground at Rochester, N. Y.

APLITE

Closely following increased output and shipments of glass products, particularly glass containers, shipments of ground "aplite" in 1944 rose 4 percent in tonnage and 7 percent in value to a new high for this product. By far the major part of the output is sold to glass manufacturers. Figures, however, may not be published, as to do so would reveal operations of individual companies.

Two firms are engaged in the processing of aplite: Dominion Minerals, Inc., Washington, D. C. (the first company to begin operations), and Carolina Mineral Co., Erwin, Tenn., an affiliate of the Consolidated Feldspar Corp., Trenton, N. J. Both companies operate grinding mills near Piney River, Va.

IMPORTS

Feldspar.—Imports of crude feldspar into the United States in 1944 were 9 percent greater in quantity and 16 percent greater in value than in 1943. Average value per long ton of imported crude spar has been steadily rising since 1940, reaching \$8.21 in 1944 compared with \$7.72 in 1943 and \$7.33 in 1942. All imports of both crude and ground material originated in Canada.

Cornwall stone.—Receipts of unmanufactured Cornwall stone in 1944 increased 18 percent in quantity and 14 percent in value compared with 1943. Average value (foreign market value) in 1944 dropped to \$13.81 from \$14.26 per long ton in 1943, or almost to the 1942 level (\$13.80). The United Kingdom remains the sole source of supply.

WORLD PRODUCTION

In addition to the United States, sizable production of feldspar has been reported in normal years from Canada, Norway, Sweden, Finland, Germany (Bavaria), Czechoslovakia, Italy, and China.

SUMMARY

Asbestos production in the United States increased considerably in 1944—to 7,558 short tons from 3,945 tons in 1943. Most of the domestic output consists of the shorter grades of chrysotile from Vermont, where operations had been suspended much of 1943 while a new quarry was being opened. Domestic sales totaled 6,667 tons, 11 percent higher than in 1943. Even with this gain in sales, the United States supplied only 1½ percent of domestic requirements.

As in the past, Canada furnished the larger part of United States needs of chrysotile, but much of it consists of shingle stock, paper stock, and other shorter nonspinning grades. Africa supplied a substantial part of the longer grades needed for military and essential civilian applications.

Chrysotile asbestos is important in the military program. The longer fibers are used for sheet packing and textiles. Asbestos textiles have many military uses to which publicity cannot be given at this time. Flameproof navy cable construction, woven friction materials, packings, and gaskets are among the more important well-known uses. Rhodesian C & G1 and C & G2 are preferred where electrical insulation is important, because these fibers are low in iron.

South Africa is virtually the sole source of the amosite and blue (crocidolite) varieties, which have important uses in the military program. Amosite is now employed extensively in manufacturing 85-percent magnesia and other high-temperature molded insulation.

The general situation improved greatly throughout the year. No serious interruption to imports occurred, and the flow of materials both from Canada and Africa was sufficient to meet all current requirements and to build up a reserve for future commitments.

In 1943 a plan was effected whereby the Metals Reserve Co. purchased, on Government account, all imported strategic grades of South African and Rhodesian asbestos for allocation to industry in accordance with the most urgent needs. In 1944 military requirements were reduced, and stocks of asbestos were regarded as adequate for prospective needs. Conditions of supply were so improved that further Government purchases were unnecessary, and they were abandoned when 1944 contracts were completed. On December 8, 1944, the War Production Board amended Order M-79 to remove all restrictions on the use of amosite and Rhodesian chrysotile. All

fibers from Rhodesia and the Union of South Africa were removed from General Import Order M-63 on February 1, 1945.

Tremolite (amphibole) asbestos is in demand for the manufacture of chemical filters, but production is very small. Anthophyllite, another variety of amphibole asbestos, finds limited use for welding-rod coatings, insulating cements, and fillers. Intermittent production is reported from scattered deposits in several States.

Salient statistics for asbestos in 1943 and 1944 are summarized in the following table.

Salient statistics of the asbestos industry in the United States, 1943-44

	1943		1944

DOMESTIC INDUSTRY

REVIEW BY STATES

Alaska.—Alaska, for the first time, has joined the commercial producers of asbestos. Deposits of slip-fiber chrysotile have been known for some time in the Dahl Creek area, Kobuk River district, but recently good-quality tremolite has been found in the same region. Some of it has already been introduced into United States markets. An important use is for making chemical filters. It was mined by the Arctic Circle Exploration Co., Candle, Alaska, and sold through Philip S. Hoyt.

An occurrence of paligorskite, an amphibole asbestos classed as mountain leather, has been discovered on Lemesurier Island, Southeastern Alaska. Lenses 6 to 8 inches wide, consisting of matted fibers resembling buckskin, occur in bed seams and cross joints in limestone. Heretofore, mountain leather has appeared only as museum specimens. A large enough tonnage may be available in this region to encourage development of commercial uses for it.

Arizona.—The total tonnage of Arizona asbestos sold in 1944 was less than one-half of that sold in 1943, but the value of sales declined only 20 percent. The higher unit value of sales in 1944 was due to the fact that the market absorbed primarily the better grades. The following companies made sales in 1944: Arizona Chrysotile Asbestos Co., Floyd Brown, Arthur Enders, and Guy Phillips—all of Globe; and Johns-Manville Products Corporation, 22 East 40th St., New York, N. Y., with mine and mill at Chrysotile.

Late in 1944 the Defense Plant Corporation stopped all work on the new custom processing mill at the Pine Top asbestos mine. This project, directed by the Southwestern Asbestos Corporation, was designed to mill and classify asbestos mined throughout the Globe area.

California.—There were two producers of asbestos in California in 1944—Kohler & Chase, miners of short-fiber chrysotile near Monticello, Napa County, and the Powhatan Mining Co. (Woodlawn, Baltimore, Md.), reporting production of tremolite asbestos near Castella, Shasta County—shipping point, Dunsmuir. Total production was much smaller than in 1943.

The Gold Meadows Mining & Milling Co. (Sacramento) reported that production would begin in 1945 at the Bowman mine near Forest-hill, Placer County. The fiber is said to be of the amphibole variety.

Georgia.—The only producer in Georgia in 1944 was the Powhatan Mining Co. from its amphibole asbestos property near Dillard, Rabun County. Philip S. Hoyt reports that several properties, both in Georgia and North Carolina, are awaiting development when labor becomes available.

North Carolina.—Sales of asbestos in North Carolina declined greatly in 1944. The Powhatan Mining Co. procured amphibole fiber from properties at Micaville, Yancey County.

Oregon.—As in previous years, small shipments of high-grade tremolite fiber were shipped from the Flora Winsenberg property at Rogue River, Jackson County. The material is used for filtering chemicals.

Vermont.—The Vermont Asbestos Mines Division of the Ruberoid Co. has opened a new quarry on the eastern shoulder of Belvidere Mountain. The asbestos-bearing rock is conveyed over the mountain to the mill by means of an overhead cableway about 1 mile long. The first large blast, fired in the new quarry about June 1, 1944, uncovered substantial quantities of long slip-fiber chrysotile. A considerable proportion of the fiber is 1 to more than 6 inches long and has superior strength and flexibility. The long asbestos fibers do not occur in isolated pockets but are abundant throughout most of a 400-foot face. Because of its unusual length, the fiber is unsuitable for carding with standard equipment, and tests have been in progress to determine the best methods and equipment to employ and the commercial applications for which the fiber is best adapted. The

discovery is of importance because it represents the only large deposit of long-fiber chrysotile found in the United States up to the present time. The mill served by the cableway operated on a two-shift basis throughout much of the year, as enough labor could not be secured to operate three shifts. Operation is suspended during the severe winter months, but plans are now under way to stock-pile enough asbestos rock to permit winter operation. The output consists chiefly of shingle stock, paper stock, and shorter grades, but spinning fibers are attaining prominence and will doubtless become increasingly important in the future. Production was much greater in 1944 than in 1943 but was still far below the maximum of which the property is capable.

TRENDS IN CONSUMPTION

The accompanying table shows for a 10-year period the domestic consumption of unmanufactured asbestos and the value of exports of asbestos products. Consumption in 1944 declined 9 percent from the record level of 1943 and was the lowest since 1940. The value of exports of asbestos products, however, gained 16 percent and reached the highest point in the history of the industry. The value of asbestos products manufactured in the United States has not been recorded since 1939.

Raw asbestos consumed in and asbestos products exported from the United States, 1935-44

Year	Raw asbestos— apparent consumption (short tons)	Asbestos products— exports (value)	Year	Raw asbestos— apparent consumption (short tons)	Asbestos products— exports (value)
1935.....	174, 655	\$2, 261, 929	1940.....	262, 199	\$3, 473, 248
1936.....	250, 922	2, 479, 273	1941.....	438, 741	4, 835, 194

¹ Revised figures.

As asbestos is used extensively for packings, gaskets, boiler lagging, and pipe covering at industrial plants and as friction material on automotive equipment, the demand for it depends to quite an extent on industrial activity. The building industry also affords an extensive market for asbestos for asbestos-cement products, heat insulation, and fireproofing. The relation of asbestos consumption to industrial production and building construction is indicated in figure 1. The similarity in the trends from 1933 to 1941 is apparent, but in 1942 military construction which dominated all building activities had reached its maximum, and the asbestos industry, operating at almost 100 percent of capacity, was unable to keep pace with it. In 1943 and 1944 military building declined rapidly, and as private construction remained very low the total construction curve dropped precipitously almost to the level of 1935. This condition influenced the downtrend in asbestos consumption to some extent. However, industrial production which was only slightly lower in 1944 than in 1943 absorbed asbestos products in such large quantities that the decline in asbestos consumption was quite moderate.

FIGURE 1.—Consumption of asbestos compared with total new construction and industrial production, 1920-44. Units are reduced to percentages of the 1935-39 average. Statistics on value of construction from Bureau of Foreign and Domestic Commerce and on industrial production from Federal Reserve Board.

MARKET CONDITIONS

Market trends were generally downward throughout the year. A moderate curtailment in demands for strategic grades in the military program had no compensating increases in other fields because building activity remained low, and there was virtually no increase in the demand for asbestos used in a multiplicity of products that normally satisfy civilian needs.

PRICES

Prices of asbestos as quoted in E&MJ Metal and Mineral Markets were unchanged throughout the year, as follows:

Per ton, f. o. b. Quebec mines, tax and bags included: Crude No. 1, \$650-\$750; crude No. 2 and sundry crudes, \$165-\$385; spinning fibers, \$124-\$233; magnesia and compressed sheet fibers, \$124-\$146.50; various grades shingle stock, \$62.50-\$85; various grades paper stock, \$44-\$49; cement stock, \$28.50-\$33; floats, \$19.50-\$21; shorts, \$14.50-\$26.50. Quotations in U. S. currency.

Per ton, f. o. b. Hyde Park, Vt.: Shingle fiber, \$62.50-\$65.50; paper stock fiber, \$44-\$53; waste, \$33; shorts, \$14.50-\$28.50; floats, \$19.50.

The following ceiling prices fixed by the Office of Price Administration for certain African fibers sold by the Metals Reserve Co. were effective in 1944: Rhodesian chrysotile C & G1 \$330, C & G2 \$236, and C & G3 \$146.50; amosite B1 \$149, B3 or D3 \$123, 3DM1 \$118, M1 \$113. These prices are per short ton at the dock in the United States. These were in effect throughout the year, but in the late summer the actual selling price of C & G3 by the Metals Reserve Co. was reduced to \$130 a ton, f. o. b. warehouse.

NEW DEVELOPMENTS

A new fire-resistant textile has been developed consisting of 72 percent asbestos, 22 percent glass fiber, and 6 percent cotton yarn. It has only half the weight per square yard of conventional asbestos cloth but has the same strength. It combines the superior flexibility of asbestos with the high tensile strength of glass wool.

Another new product under development for some time reached the commercial production stage in 1944. It is classed as a lime-silica high-temperature insulation. It contains 15 percent of asbestos fiber as a binder, and its temperature limit is said to be about 1,200° F.

POSTWAR OUTLOOK

Asbestos has a multitude of uses, and most of its applications during wartimes have their peacetime counterparts. No asbestos mines in the world were damaged by war. Nearly all worked at capacity during the war period. All mines will be available at the close of the war to supply raw material to asbestos-product factories throughout the world. Although war demands for asbestos will diminish (they have already declined greatly in the field of Navy cable construction, for example) peacetime needs will create an enlarged demand. Asbestos-products plants in occupied countries that have been unable to obtain raw material will need large supplies. Early in 1945 an order was placed for 3,085 tons of Canadian spinning and shingle fibers to be shipped to France. This is doubtless a forerunner of many similar orders as Belgium, Holland, Italy, and other countries take steps to reestablish their industries. New factories are also in prospect for making asbestos-cement products in Mexico, South and Central America, Australasia, and the United States. It is reported that 13 asbestos-cement-products plants are now in operation in Central and South America. Reconversion of automobile factories to the manufacture of commercial and pleasure vehicles will shift the demand for friction materials from military to civilian needs. The enormous backlog of residential and commercial building foreshadows a huge demand for asbestos-cement products. It is evident therefore that, although transition from a wartime to a peacetime economy may shift the emphasis of asbestos requirements from certain fields of use to others, the general effect will be an increasing demand, particularly for shingle-stock and cement-stock grades.

The demand for spinning fibers in the immediate postwar period probably will be strong, but from the long-range viewpoint these grades have a less promising future than the shorter fibers. There have been no noteworthy new developments that point to an expansion in use of asbestos textile products. On the other hand, there is a decided drift from woven to molded brake linings, and from woven gaskets and packings to other types that employ shorter-grade fiber. Some competition from fibrous glass is to be expected, but it is quite unlikely that glass will invade the field of friction materials or packings. Spinning fibers generally constitute a minor part of the output of asbestos mines; nevertheless, they are the most profitable products, and the prospect of reduced demand for them is a problem worthy of careful consideration by all asbestos producers.

FOREIGN TRADE¹

The following table shows imports of unmanufactured asbestos into the United States in 1943 and 1944. Total imports show a decline of 9 percent in quantity and nearly 20 percent in value. The largest relative declines were in imports from Rhodesia and the Union of South Africa. Imports from all major sources except Soviet Russia were less in 1944 than in 1943. Receipts from that source increased greatly. The general decline in imports of the better grades of fiber reflects the improved supply situation with respect to military and essential civilian needs.

¹ In addition to countries listed asbestos is produced in Algeria, Bulgaria, Czechoslovakia, Egypt, Madagascar, Spain, and Switzerland.

² Data not available.

³ Exports.

⁴ Exclusive of sand, gravel, and stone (waste rock only), production of which is reported as follows: 1937, 3,611 tons; 1938, 2,975 tons; 1939, 3,535 tons; 1940, 5,880 tons; 1941, 7,669 tons; 1942, 7,339 tons; 1943-44, data not available.

⁵ Includes asbestos flour.

⁶ Imports into United States.

⁷ Preliminary.

⁸ January to June, inclusive.

⁹ Statistics compiled by B. B. Waldbauer.

CANADA

The Canadian asbestos industry is centered in the Thetford Mines area of the Province of Quebec. Although operations have been conducted on a large scale for many years the reserves are still very great. War demands for the longer grades were strong throughout the year both in the United States and in Great Britain, but building construction was so curtailed that demands for the shorter grades, particularly cement stock, were reduced. As most of the Canadian production is of the shorter grades, the output declined about 10 percent compared with 1943. The falling off in production of crude fibers is noteworthy. Production of crudes in 1944 fell below 2,000 tons for the first time since the early days of the industry. Operations at the King mine of the Asbestos Corporation, Ltd., have been described in some detail.³

Canadian Johns-Manville has undertaken an extensive program of underground mining by the block-caving method. Shaft sinking is now in progress.

The following figures have been released by the Dominion Bureau of Statistics.

AFRICA

North Africa.—A deposit of chrysotile is reported at Bou Asser, French Morocco. Reports received by the Bureau of Mines show production of 116 metric tons in 1942 and 182 tons in 1943. A sample received by the Bureau is a section of a cross-fiber vein having fibers about 2 inches long and apparently of good spinning quality. It is used locally in the manufacture of building products at Casablanca.

Southern Rhodesia.—No figures for Rhodesian asbestos production have been published since May 1940. Export data, which are available for certain years, are an approximate measure of production because local consumption is quite small. The following table shows export figures now at hand.

³ McLaren, D. C., The King Asbestos Mine: Canadian Min. Jour., October 1944, pp. 683-687.

Asbestos exported from Southern Rhodesia, 1940-44

¹ Data not available.

Swaziland.—Since June 1939 the Havelock mine in Swaziland has been an important producer of chrysotile. Production during recent years in metric tons is indicated in the preceding World table.

Union of South Africa.—Amosite, the principal variety of asbestos mined in the Union of South Africa, is produced nowhere in the world except in the Transvaal. Crocidolite (blue asbestos) is also an important product. Chrysotile production was important a few years ago, but the deposits then worked are virtually exhausted.

OTHER COUNTRIES

No recent data on the Russian asbestos industry are available.

According to reports received by the Bureau of Mines, Turkey has produced small quantities of asbestos as follows. Quantities are metric tons, and values (in parentheses) are Turkish lira: 1940, 99 (2940); 1941, 146 (4380); 1942, 295 (14650); and 1943, 133 (12502).

The new asbestos mill near Tinaquillo, Venezuela, under construction for some time, has not been completed.

BARITE, WITHERITE, AND BARIUM CHEMICALS

SUMMARY

Record quantities of barite were produced and consumed in the United States during 1944. Output was 515,136 short tons—20 percent over 1943 and 7 percent greater than in the previous record year 1941. Consumption (595,563 tons) included 67,888 tons of imports, largely from Nova Scotia. The greatest increase in production was in Arkansas, where two barite-flotation plants expanded their capacity early in the year in response to an accelerated demand for barite in oil-well drilling muds. Production was also up in Missouri, assisted by a rise in price ceiling from \$7 to \$8.50 a short ton of crude barite and by wage increases from 10 to 15 cents an hour. Despite the exhaustion of one of the larger deposits in Georgia, production was higher than in 1943. Tennessee output was down owing to price and labor difficulties. Equipment shortages worked hardships on producers, particularly in Missouri and eastward. Lack of tires and trucks was the major complaint. In the West, production was easier, though labor was likewise scarce. The main producer on the West coast was threatened with a shutdown when its carrier, the Yosemite Valley Railroad, filed a petition to abandon with the Interstate Commerce Commission. The action is pending.

Stocks of crude barite in the hands of producers at the end of the year were low in the East but adequate in the West. Late in the year some material was shipped East from a Nevada stock pile.

Sales of ground and crushed barite reached a new record, 344,757 short tons—a 66-percent increase over 1943. Grinding activity for the Gulf market was intense. In addition to expansions in the two Arkansas flotation plants, a new grinding mill was erected in Missouri. Well drilling is now the largest use of barite, taking 54 percent of crude production in 1944. Despite the increase in production, an unprecedented number of wells blew out in 1944, indicating that some drillers

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

at times were rushing their programs ahead of barite availability. Crushed barite, used mainly for glass, was likewise in short supply.

War demands continued to drive the barium-chemicals industry to the highest levels permitted by the shortage of barite and manpower. Barium nitrate production, negligible before the war, was in demand for the new thermate incendiary bombs destined for Japan. Barium chloride and carbonate were required for heat-treating metal parts. Much barium sulfate was used in coating photographic papers for the services. Demand for lithopone was greater than supply.

BARITE

CRUDE

PRODUCTION AND CONSUMPTION

With isolated exceptions, the measures taken in 1943-44 by the War Production Board, the Office of Price Administration, and the War Labor Board to increase barite production bore fruit. The labor

shortage was eased to some extent by wage increases approved by the War Labor Board first in the Tennessee-Georgia area,² then in Missouri. Based on these increased production costs the Office of Price Administration permitted increases in the ceiling price of barite in Tennessee, Georgia, and Missouri.

The consumption of barite in 1944 was 595,563 short tons, distributed as follows: For well drilling, 277,792; for chemicals, 100,921; for lithopone, 134,597; for glass, 24,153; for paint filler, 23,000; for rubber filler 10,000; and for other purposes, including grinding losses, 25,100.

The apparent new supply of barite in the United States since (production plus imports) is shown in figure 1.

FIGURE 1.—Apparent new supply of barite in the United States, 1900-1944.

Spurred by well-drilling requirements, Magnet Cove Barium Corp. completed a second flotation plant at Malvern, Ark., and the National Lead Co. expanded several units in its existing plant. The Bureau of Mines diamond-drilled the Magnet Cove, Ark., area extensively and mapped out additional reserves of several million tons.

Industrial Minerals & Chemical Co. has stripped thousands of tons of barite at its Spanish mine near Washington, Nevada County, Calif., since 1940, and about 10,000 tons remain to be mined before further stripping is required. The producer states that total reserves may reach 200,000 tons. Barite produced here is used in barium chemicals and well drilling. A very high grade material is offered for use in glass, paint, and white rubber goods.

The L. A. Wood Co. removed the last minable barite from its Cartersville (Ga.) open-cut in February 1945. This cut was mined

² Bureau of Mines Minerals Yearbook, 1943, p. 1488.

for years by the Barium Reduction Corp. followed by the Cartersville Barium Co., then the L. A. Wood Co. Barite produced here was converted to black ash in Cartersville for shipment to a barium-chemicals manufacturer, and the loss of production was keenly felt in the early months of 1945.

Several new washers were built or building in 1944 in the Washington County area of Missouri. The National Lead Co. built two washers of radical bowl design, intended to reduce loss of fines. De Soto Mining Co. and Cordia Mining Co. completed new washers. The L. A. Wood Co. of Sweetwater, Tenn., bought out the M. & B. Mining Co. at Palmer, Mo., and also planned to build an additional washer, closer to the Potosi area. Other new washers were operated by Superior Minerals Co. at Richwoods, Mo., and Star Mining Co. at Potosi, Mo.

A new grinding plant was erected for the well-drilling trade by Eversole Maclay, Mineral Point, Mo.

The Clinchfield Sand & Feldspar Corp. reopened barite veins near Del Rio in Cocke County (Burnett Station, Southern Railway) and is shipping filler-grade barite to Kings Creek, S. C., for grinding and sale.

PRICES

Prices in Tennessee, Georgia, and Missouri were higher in accordance with the new ceilings established by the Office of Price Administration April 8 and July 26, 1944. Under the new ceilings chemical-grade barite in Georgia and Tennessee may be sold at \$10, \$10.50, or \$11 a long ton, f. o. b. washer loading point, depending on the individual producer. On glass barite the L. A. Wood Co. was given a ceiling of \$12.50 a long ton, f. o. b. Sweetwater, Tenn., or Cartersville, Ga., and New Riverside Ochre Co., a ceiling of \$11.50 a short ton, f. o. b. Cartersville. The Missouri ceiling of \$8.50 a short ton applies to all Missouri producers, and differences in grade are accounted for by a premium-penalty system.³

WORLD PRODUCTION

Data on production of barite in foreign countries have been meager since the outbreak of war. Germany was the world's largest producer in prewar years, furnishing about half the output. Now it appears likely that loss of foreign markets for German crude barite, lithopone, and barium chemicals and the recent production increases in Arkansas have placed Germany second to the United States.

World production of barite, 1937-44, by countries, in metric tons¹

⁴ Official figures which, it is reported, cover only output of mines included under the mining law.

⁵ Estimate.

⁶ January to June, inclusive.

⁷ Includes witherite.

⁸ Office of Price Administration Amendment 6 to M. P. R. 327; July 26, 1944.

GROUND (AND CRUSHED)

SALES

The footage of high-pressure oil wells drilled in 1944 was about 90 percent greater than in 1943. Accordingly, a substantial increase in shipments of ground barite to the oil fields was not unexpected. Barite is mixed in rotary drilling muds to exert back pressure on high-pressure oil and gas formations. About 5 tons of barite is used for each 1,000 feet of high-pressure drilling, and the cautious driller will suspend operations unless he has adequate stocks of barite on hand or knows that he can get it. Nevertheless, there was an unprecedented wave of blow-outs in 1944, some of which may have been caused by lack of barite.

Late in 1943 and early in 1944 the shortage of crushed barite for use in glass was so severe that glassmakers resorted to less-desirable ground well-drilling grades. Production of the crushed grade increased later in the year, however, releasing the well-drilling grades to the oil fields, where they were badly needed.

Ground (and crushed) barite sold or used by producers in the United States, 1940-44

	1940	1941	1942	1943	1944
Plants.....	16	16	19	18	19
Short tons.....	184,390	234,877	178,765	208,252	344,757
Value.....	\$3,697,806	\$4,606,832	\$3,611,745	\$3,743,919	\$5,455,835

A considerable quantity of ground barite is bleached for use as a filler in white paints, rubber, cloth, wall paper, printing ink, and plastics. Unbleached barite may be used where a brown filler is permissible—for example, in linoleum, phonograph records, rope finishing, asbestos brake lining, dark paints, and rubber.

Ground (and crushed) barite sold or used by producers, 1942-44, by consuming industries

Industry	1942		1943		1944	
	Short tons	Percent of total	Short tons	Percent of total	Short tons	Percent of total
Well drilling.....	117,380	66	144,452	69	277,792	80
Paint.....	18,484	10	15,000	7	23,000	7
Glass.....	21,895	12	25,464	12	24,153	7
Rubber.....	6,334	4	8,000	4	10,000	3
Undistributed.....	14,672	8	15,336	8	9,812	3
	178,765	100	208,252	100	344,757	100

In the foregoing table figures for consumption of ground barite in "Paint," "Rubber," and "Undistributed" have been estimated partly by the grinders and partly by the Bureau of Mines.

PRICES

The average price per short ton of ground barite—\$15.83 in 1944 and \$17.98 in 1943—was much lower than in 1942 and previous years, when a royalty of \$13 per ton was included in the price of barite used

in well drilling. The patent on which the royalty was based expired in 1943. Ground, bleached barite, according to the Oil, Paint, and Drug Reporter, was quoted at \$25.35 a short ton in bags, carlots, at St. Louis, Mo. Unbleached material was quoted at \$17.50 a short ton f. o. b. producing plant. Crushed barite for glass was sold under ceilings of \$11.50, \$12.50, and \$13 a long ton f. o. b. producing plants in Georgia and Tennessee, depending on the producer: A differential of about \$2 a ton was generally added for bagging.

WITHERITE

Little or no commercial witherite was on the market in 1944. None was imported from England—normally the world source—and the industry used the more expensive precipitated barium carbonate as an antiscumming agent in ceramics. The Baroid Sales Division of the National Lead Co. mined a mixed witherite-barite near El Portal, Calif., and ground the material without separation for oil-well drilling muds. The production of this mixture is reported as barite.

Witherite, crude, unground, imported for consumption in the United States, 1940-44

(Value at point of shipment)

Year	Short tons	Value	Year	Short tons	Value
1940.....	3,584	\$70,126	1943.....	448	\$9,452
1941.....	4,790	107,238	1944.....		
1942.....	3,066	60,824			

According to the Oil, Paint and Drug Reporter, witherite, 99 per cent through 200-mesh, bags, carlots, works, was nominally quoted at \$43 a short ton in 1944.

BARIUM CHEMICALS

PRODUCTION

Barium chemicals are used directly or indirectly for many war and essential civilian purposes. Lithopone was in heavy demand in 1944 and helped to relieve shortages of the more opaque titanium, zinc, and lead pigments. Barium chloride is one of the principal barium salts. Besides being a source of other barium chemicals, it is used in heat-treating steel, in purifying salt brines for chlorine and sodium hydroxide manufacture, and in the manufacture of coatings for photographic paper. Blanc fixe (precipitated barium sulfate) is used as a filler in white paint, rubber, linoleum, and other materials. Barium carbonate is used as a carbon carrier in case-hardening steel, in preventing efflorescence in structural bricks, and as a starting point in making other barium compounds, including the nitrate, oxide, peroxide, and hydroxide. The nitrate is used in green signal flares and explosives, the oxide in case-hardening steel, the peroxide in making hydrogen peroxide, and the hydroxide in beet-sugar purification.

In the following table, dealing with production, use, and sales of barium chemicals by the barium-chemical industry, which first appeared in this chapter reviewing 1943, it has been decided to omit barium sulfide, virtually all of which exists only in solution, and to add black ash produced by lithopone and chemical manufacturers.

Barium chemicals produced and used or sold by producers in the United States, 1941-44, in short tons

Chemical	Plants	Produced	Used by producers in other barium chemicals ¹	Sold by producers ¹

POSTWAR OUTLOOK

Well drilling has been the largest use of barite in most years since 1938 and probably will continue in this preeminent position after the war. Demand for barite in lithopone is very difficult to predict. The lithopone industry has run at capacity during the war but must eventually face competition from the more opaque titanium pigments. The lithopone industry should survive as long as titanium dioxide is sold at 15 cents a pound and lithopone at 4½ cents. The barium-chemicals industry doubtless will cease making a few items, such as the nitrate, which were used solely for military purposes, but production of the chloride, carbonate, sulfate, and hydroxide should continue in but slightly reduced volume for civilian needs. The barite supply in all parts of the country is adequate save on the Atlantic coast, where reduction of output in Tennessee has already necessitated imports. Unless new deposits are found in Tennessee and Georgia, supplementary barite must be brought into eastern markets from Nova Scotia, Germany, or Missouri. The following table compares the costs of barite from the sources mentioned.

Costs of delivering a short ton of chemical-grade barite to certain cities in the eastern United States, July 1944

[Unloading and handling charges and insurance are not included on the ocean shipments. The unloading and handling charge on Nova Scotia barite received at Baltimore is \$1.13, insurance is \$0.03, and miscellaneous \$0.35]

GENERAL CONDITIONS

New records have been made in the annual production and sales of domestic potassium salts. In 1944, 1,578,498 short tons of marketable

FIGURE 1.—Production of marketable potassium salts in the United States, 1933-44.

potassium salts containing 834,568 tons of equivalent potash (K_2O) were produced. (See fig. 1.) A somewhat smaller quantity (1,543,420 tons), likewise a record, was sold; according to the producers, this material contained 817,892 tons of equivalent potash. Stocks of potassium salts, in terms of K_2O in producers' hands at the end of 1944, were more than double those of 1943 and larger than in any recent year. Exports of both fertilizer and chemical potash were less in 1944 than in 1943. Imports of potash for fertilizer purposes were much less than in 1943, but those for chemical use were larger. Domestic consumption of potash made a new record—about 753,000 short tons of K_2O .

A general summary, by Turrentine,¹ of the American potash industry under wartime conditions, appeared late in 1944.

¹ Turrentine, J. W., The American Potash Industry Meets Its Wartime Test: Chem. and Eng. News, vol. 22, No. 22, Nov. 25, 1944, pp. 1994-1998.

¹ Estimate by Bureau of Mines.² Quantity sold by producers, plus imports, minus exports.³ Revised figure.

Potash Allocation Order M-291, which was to have expired May 31, 1944, was amended April 3, 1944, and extended for another 12 months. Effective March 22, 1945, all primary potash salts (muriate of potash, sulfate of potash, sulfate of potash-magnesia, and run-of-mine potash) were removed from Allocation Order M-291 and placed under General Chemicals Order M-300.

POSTWAR OUTLOOK

The present domestic potash mines can produce more than normal domestic requirements under peace time conditions. Availability of foreign supplies after the war will limit foreign markets for American potash, and certain of these potash-producing nations may enter the domestic market in competition with American companies, especially if it is considered advisable to restrict domestic production to conserve our known potash resources. The enlarged food-production programs probably will maintain domestic potash output at high levels for some time.

DOMESTIC RESERVES

The domestic potash industry is based largely upon the sylvite (KCl) deposits of the Carlsbad (N.Mex.) region; the potassium-bearing brines of Searles Lake, Calif., and Salduro Marsh, Utah; and the langbeinite ($K_2SO_4 \cdot 2 MgSO_4$) deposits of the Carlsbad region. Estimates made about 1940 placed the total known resources of water-soluble potash in the above deposits at around 90 million tons K_2O , adequate for only about 100 years at the present rate of consumption. Even on the basis of these early estimates the Committee on National Fertilizers and Lime Policy urges ² that greatly intensified efforts be made by the Federal Government to discover new domestic sources of

² Committee on National Fertilizers and Lime Policy, U. S. Department of Agriculture and War Food Administration, A National Policy for Fertilizers and Liming Materials: Washington, D. C., February 1945, 11 pp.

water-soluble potash on public land; that, until vastly larger deposits are discovered, our limited known resources be looked upon as a strategic reserve; and that, if extensive new deposits are not located soon, further vigorous steps be taken to curtail the use of American deposits and replace them with imports.

Most of the known domestic potash reserves are in the Texas-New Mexico field. According to estimates made in 1940 these beds contain 75,000,000 tons K_2O . Such estimates were based on beds of potash salts 4 feet or more in thickness which analyze at least 14 percent K_2O . Mansfield and Lang,³ after calling attention to the fairly wide distribution of sylvite in this field, state that:

The richer sylvite beds are localized in four known minor areas which have been prospected in some detail and which are surrounded by barren or relatively barren ground. Such prospecting as has been done outside of these areas has not thus far led to any very encouraging results, but it is quite possible that other rich localities may be discovered. . . .

Three of these known areas are now being mined, and the fourth was prospected by the Government in 1944. The reserves in the areas now producing are being rapidly exhausted. A recent article⁴ states that:

Apparently the four major companies [three of which are in the New Mexico field] can continue for perhaps 10 to 15 years at present rates without exhausting the reserves to which they have acquired rights.

The rights referred to were acquired before the new regulations promulgated by the United States Department of the Interior in January 1945. The Government drilling in the fourth area in the Carlsbad region proved up only a few million tons of K_2O . The known economically recoverable potash reserves in this field therefore appear quite limited.

With reference to national security, even in the near future, further search for deposits of soluble potash is urgently needed. Probable areas where such deposits might be found include the Texas-New Mexico field, the Grand County (Utah) field, and eastern United States. Possibilities are definitely known in the first two fields. The salt deposits of eastern United States have never been tested for potash beds by core drilling, although well brines show significant quantities of potash, and salt beds containing 8 percent KCl have been found in Nova Scotia, northeast of this area.

PRODUCTION AND SALES

The annual increase in production of marketable potassium salts in the United States since 1934 was once more evident in 1944. Again it was large, 149,658 tons more being produced in 1944 than in 1943, and the approximate equivalent K_2O content of the production was 95,427 tons greater. Sales exceeded a million and a half (1,543,420) tons in 1944 and were a little more than 10 percent over those in 1943. The contained equivalent potash (K_2O) was 817,892 tons, an increase of nearly 12 percent over 1943. Production exceeded sales; producers' stocks were again larger at the end of the year than at the beginning and larger than in several recent years. The average value of the potassium salts sold in 1944 was \$19.11 per ton.

³ Mansfield, G. R., and Lang, W. B., The Texas-New Mexico Potash Deposits: Univ. Texas Bull. 3401, 1935, pp. 641-832. (See p. 682.)

⁴ McBride, R. S., Wootton, Paul, and Burton, Malcolm, Watching Washington: Chem. and Met. Eng. vol. 52, No. 3, March 1945, p. 82.

Production of all types of marketable potassium salts listed in the following table, except manure salts, was larger in 1944 than in 1943.

Potassium salts produced in the United States, 1942-44, by grades, in short tons

¹ Includes refined potash.

The potash industry retains its western character. Virtually all the 1944 output came from California, New Mexico, and Utah, largely from the deeply buried Permian saline sedimentary deposits of New Mexico. Only a small quantity (a byproduct of cement operations in Maryland) came from the Eastern States. The domestic potash salts sold in 1944 were largely refined or processed products.

The potash-producing companies in the United States in 1944, by States, were as follows:

California:

The American Potash & Chemical Corp., 122 East Forty-second Street, New York City (plant at Trona, on Searles Lake, Calif.).

Maryland:

North American Cement Corp., 41 East Forty-second Street, New York City (plant at Security, Md.).

New Mexico:

International Minerals & Chemical Corp., 20 North Wacker Drive, Chicago, Ill. (mine and plant near Carlsbad, N. Mex.).

Potash Company of America, Carlsbad, N. Mex. (mine and plant near Carlsbad, N. Mex.).

United States Potash Co., Inc., 30 Rockefeller Plaza, New York City (mine and plant near Carlsbad, N. Mex.).

Utah:

Bonneville, Ltd., 540 West Seventh South, Salt Lake City, Utah (plant near Wendover, Utah).

CONSUMPTION

Consumption of potash salts in the United States and its possessions in 1944 was approximately 753,000 tons of K_2O . The following table, based largely upon deliveries of potash of domestic origin as reported by the American Potash Institute, indicates actual sales of 752,332 tons for domestic consumption in the United States. Apparent consumption, calculated by subtracting exports from the

FIGURE 2.—Comparison of apparent domestic consumption of potash (K_2O) and sales by domestic producers of potash in the United States, 1925-44.

sum of the imports and producers' sales, was 753,893 tons of K_2O in 1944.

Apparent domestic consumption of potassium salts, in terms of equivalent potash (K_2O), and its relationships to sales of domestic producers, as reported to the Bureau of Mines for a period of years, are shown in figure 2.

According to figures of the American Potash Institute on potash deliveries, 89 percent of the domestic deliveries of American potash in 1944 went to the fertilizer industry and 11 percent for chemicals.

Sales of potash in the United States for consumption and export, 1942-44, in short tons of K_2O

PRICES

Price lists for the 1944-45 fertilizer season were released by the major potash companies on dates ranging from April 1 to May 15, 1944. Most of the schedules covered the period from June 1, 1944, to May 31, 1945. The following base prices were reported by the various producing companies:

Muriate of potash (62 to 63 percent; 62 percent K_2O minimum).	53½ cents per unit K_2O .
Muriate of potash (60 percent K_2O minimum).	53½ cents per unit K_2O .
Muriate of potash, granular (50 percent K_2O minimum).	53½ cents per unit K_2O and in the first issued schedule 56 cents per unit K_2O (later reduced to 53½ cents).
Muriate of potash, granular (48 to 52 percent, 48 percent K_2O minimum).	53½ cents per unit K_2O .
Manure salts:	
22 to 26 percent K_2O , 22 percent K_2O minimum, run-of-mine.	20 cents per unit K_2O .
22 percent K_2O minimum.	20 cents per unit K_2O .
Sulfate of potash (90 to 95 percent K_2SO_4 , basis 90 percent K_2SO_4).	\$36.25 per short ton.
Sulfate of potash-magnesia (basis 40 percent K_2SO_4 , 18.50 percent MgO).	\$26.00 per short ton.

Maximum Price Regulation 404—Potash, effective June 18, 1943, providing for maximum prices of potash, was in effect until July 5, 1944, when it was superseded by Revised Maximum Price Regulation 205 (Fertilizer Raw Materials) of June 30, 1944. Muriate of potash, manure salts, sulfate of potash, and sulfate of potash-magnesia were covered in the new regulations, as in the old. No changes were made in the base prices.

Retail prices of potash were covered during 1944 by Second Revised Maximum Price Regulation 135 of November 17, 1943; Second Revised Maximum Price Regulation 135, Including Amendment 1, of January 5, 1944; and Second Revised Maximum Price Regulation 135 as amended July 26, 1944.

REVIEW BY STATES

General.—In 1944 merchantable potash salts were produced in four States—California, Maryland, New Mexico, and Utah. The output of the States (except New Mexico, where there were three companies) cannot be given separately without disclosing individual company returns. New Mexico was by far the largest domestic producer, furnishing 85 percent of the total. California, although a much smaller producer than New Mexico, furnished considerably more than the combined output of the other two States.

A program for converting potassium chloride to potassium sulfate was initiated by the Government in November 1944 to supplement the supply of potassium sulfate, particularly in tobacco-producing areas. Potassium chloride was to be substituted for sodium chloride in the production of hydrochloric acid at the Rubber Reserve Co. plant at Louisville, Ky. The plan was abandoned, however, shortly after the start of operations, because of a break-down of the acid-producing facilities.

Discovery of metals of the platinum group in western alunites has been reported.⁵ Traces of platinum metals are said to have been

⁵ Cress, S. H., and Feldman, Cyrus, *Platinum Minerals Identified in Western Alunite*: Eng. and Min. Jour., vol. 144, No. 12, 1943, p. 106.

identified in alunite samples from Sugar Loaf Peak, Yuma County, Ariz., and Marble Mountain, Rio Grande County, Colo. Traces of rubidium are also reported in a few samples and traces of gallium in nearly all samples examined.

California.—The American Potash & Chemical Corp. (122 East Forty-second Street, New York City), only producer of potash in California, is reported to have enlarged its plant at Searles Lake and to have improved the refining process. Descriptions of the operations have appeared in two articles⁶ and in a large, illustrated booklet issued by the company. The stock of the company remained vested in the hands of the Alien Property Custodian, although rumors of a proposed offering of the stock for sale appeared in financial journals about midyear.

Since January 1944 the Western Electrochemical Co. has been producing potassium perchlorate in Los Angeles. Descriptions of the plant appeared late in the year.⁷

Maryland.—Only one company in Maryland produced byproduct potash for agricultural use in 1944. This was the North American Cement Corp. (41 East Forty-second Street, New York City) which at its plant at Security, Washington County, a short distance east of Hagerstown, recovered impure sulfate of potash from cement-kiln flue dust.

New Mexico.—Mine production of potash salts in the Carlsbad region of New Mexico continued to increase in 1944, and another record was made. The three companies operating in this area mined 3,749,250 tons of sylvinite and crude langbeinite combined—316,007 tons more than in 1943. The average equivalent K_2O content of the mined salts increased from 21.19 percent in 1943 to 21.33 percent in 1944. The average equivalent K_2O content of the sylvinite mined was 22.9 percent in 1941, 22.7 percent in 1942, 22.6 percent in 1943, and 22.7 percent in 1944.

All three companies mined sylvite (potassium chloride) and one—the International Minerals & Chemical Corp.—mined also langbeinite (a potassium-magnesium sulfate). The greater part of the mined production was sylvite, most of which was processed to yield 60-percent or higher-grade K_2O muriate. The production of merchantable potash salts in New Mexico in 1944 was 1,337,459 tons (85 percent of the total domestic production), with an equivalent K_2O content of 694,872 tons (83 percent of the total production). Sales were 1,304,497 tons (85 percent of the United States total), with an equivalent K_2O content of 679,721 tons (83 percent of the domestic total) and valued at \$24,739,507. Muriate of potash was produced by all three companies. Potassium sulfate and potassium-magnesium sulfate (sulfate of potash-magnesia) were produced from crude langbeinite by the International Minerals & Chemical Corp. in the refinery at its mine near Carlsbad. Potassium sulfate was produced also by the Potash Company of America.

The abundance of magnesium in 1944 brought about the closing of the magnesium-metal plant at Austin, Tex., in that year; as a result,

the Defense Plant Corporation found it unnecessary to continue its production of magnesium-chloride cell feed for the Austin plant from potash salts at its Carlsbad (N. Mex.) plant, adjacent to the refinery of the International Minerals & Chemical Corp., and operations there were stopped in May 1944, after that plant had been in operation about 11 months. Detailed descriptions of this magnesium chloride plant have been published.⁸

In February 1944 the United States Department of the Interior obtained bids for drilling on, and in the vicinity of, the Potash Reserve established in the Carlsbad region by Executive order in 1931. To determine the extent and richness of this particular deposit, 16 core holes were drilled by the Bureau of Mines in cooperation with the Geological Survey. Drilling was begun about March 1, 1944, and work on the project was completed in October 1944. A few million tons of possible profitably minable potash salts, containing over 20 percent K_2O , were disclosed by the drilling operations.

Following the suggestion of A. D. Mackay of New York that cesium or rubidium might be found associated with the langbeinite of the Carlsbad area, spectrographic analyses for these elements were made by the Eastern Experiment Station of the Bureau of Mines on specimens of carnallite, langbeinite, and sylvite from that area. Rubidium was found in all three minerals. The largest quantity, around 0.5 percent of rubidium oxide, appeared in the carnallite. Cesium was found in the sylvite alone and only in traces. Further studies of the occurrence of these two elements in this field are needed to determine whether, in the processes now in use or in future technology, they could be recovered profitably. In the Stassfurt region, Germany, the carnallites contain only small percentages of cesium and rubidium, but these deposits are important sources of the metals because their salts become concentrated in the large-scale extraction of potassium chloride.

The geology of the potash-bearing area was discussed by Adams⁹ in an article published late in 1944. The use of shuttle cars in the mine of the International Minerals & Chemical Corp. was described by Harley¹⁰ and in that of the Potash Company of America by Haworth.¹¹

The commercial possibilities and technology of the Texas-New Mexico polyhalite deposits are discussed by Conley and Partridge in a Bureau of Mines bulletin issued in 1944.¹²

Utah.—Of the several types of potash occurrences in Utah, only the potassium-bearing brines were in commercial production in 1944. Bonneville, Ltd. (Salt Lake City) continued to produce potassium chloride from Salduro Marsh brines at its plant near Wendover, Tooele County, in northwestern Utah. Production was much above

that in 1943 and even exceeded the previous peak of 1942. A detailed description of the operations was published near the end of the year.¹³

Some development work was carried on in 1944 on the alunite deposits of the Marysville district, Piute County. The Bureau of Mines began operations in May and completed its exploratory work late in October. The earlier work, consisting of surface trenching, diamond drilling, and sampling, was on the White Hills claims. Later, trenching and sampling were done on some of the other claims. Kalunite, Inc. (Box 238, Salt Lake City), did no mining at its Empico (White Horse) mine at Marysville but shipped crude alunite from stock at the mine to its Salt Lake City alumina plant, where it was milled. The Salt Lake City plant was operated only on an experimental basis, production being used in building up the circuit. There were no sales of the products. A description of the plant by the technical director, Arthur Fleischer, was published during the year.¹⁴

No development work is known to have taken place in 1944 in the Grand County potash field in eastern Utah. In February 1944 B. W. Dyer¹⁵ presented a paper before the New York meeting of the American Institute of Mining and Metallurgical Engineers describing the results of drilling operations in the Crescent Eagle, Salt Valley, Seven Mile, Cane Creek, and Salt Wash areas in eastern Utah.

Public Land Order 130, issued May 26, 1943, which temporarily, withdrew and reserved certain public lands in Utah, therein described, for classification and for prospecting and development under the mineral leasing laws, was revoked by Secretary of the Interior Harold L. Ickes on January 4, 1945, in Public Land Order 256. Subject to valid existing rights, the public lands contained in certain specified areas totaling approximately 210,650 acres, were withdrawn from all forms of appropriation under the public lands laws, including the mining and mineral-leasing laws, and reserved for classification under the jurisdiction of the Secretary of the Interior.

FOREIGN TRADE¹⁶

Imports.—With the continuance of World War activities, imports of potash salts in 1944 remained at the recent low levels, a total of only 19,141 short tons (4,868 tons K_2O) being imported. The total value of imports, however, jumped to \$2,048,351 because of the importation of considerable quantities of high-valued argols and cream of tartar. Chile, U. S. S. R., Algeria, and Argentina were the principal sources of imports.

Potash (K_2O) for fertilizer use constituted only 77.2 percent of the total imports in 1944, whereas in 1943, with the decline in bitartrate imports, fertilizers had formed 99.4 percent of the total. Imports for chemical use rose in 1944 to 22.8 percent of the total, largely because of the increased argols imports.

Potassium-sodium nitrate (Chile) was the principal potash salt imported in 1944 for fertilizer use—9,407 tons (1,317 tons K_2O) out of the total of 13,739 tons of fertilizer salts (3,760 tons K_2O) imported.

¹ Approximate equivalent as potash (K₂O)-1943: 55 percent; 1944: 40 percent. ² Less than 1 ton.² United Kingdom of Great Britain and Northern Ireland.

Imports of potassium chloride (muriate) in 1944 were almost entirely from the U. S. S. R. Imports of potassium-bearing materials for consumption in the chemical industries consisted largely of potassium bitartrate as argols and cream of tartar from numerous countries but principally Algeria, Argentina, and Portugal.

Exports.—The total value of the domestic export trade in potash materials fell from over 7 million dollars in 1943 to \$6,238,416 in 1944, declines being registered in the values of both fertilizer and chemical exports; the decrease, however, was mostly in the value of the chemical materials. The total quantity of fertilizer potash materials exported in 1944—110,057 short tons—was only slightly less than in 1943; the total value still exceeded 3 million dollars. The fertilizer exports went largely to Canada (85,215 tons), with smaller amounts to other countries. Exports of chemical potash materials totaled only 15,419 tons, with a value just over 3 million dollars. The principal potash materials exported were the hydroxide (caustic potash), nitrate and mixtures, chlorate and mixtures, and the carbonate and mixtures. The United Kingdom, Canada, Brazil, and U. S. S. R., in the order named, were the leading recipients of the potash chemicals exported in 1944.

³ Less than 1 ton.

⁴ United Kingdom of Great Britain and Northern Ireland.

WORLD PRODUCTION

Production returns are available for but few foreign countries in recent years. Operations have been in progress, however, in several countries. Soviet Russia, with its large reserves in the Solikamsk region, controls the potash industry of eastern Europe, and in 1944 the capture of the Polish potash fields added to its reserve. Fersman ¹⁷ in a recent article refers to the discovery of the Solikamsk deposits as giving rise to the establishment of the world's largest potassium industry and describes the Soviet deposits of potassium salts as the most extensive known in the world, 35 times as great as all other known reserves. He considers the Solikamsk deposits able to supply the entire world demand for potassium fertilizers for many thousands of years.

In Western Australia the output of potash from the Lake Champion alunite deposits late in 1944 is reported as about 5 tons daily, with modifications of the plant in process to raise the daily output to 13 tons.

Potash deposits were discovered in exploratory work at the Malagash salt mine in Nova Scotia in 1944. Reserves are estimated as several hundred thousand tons containing an average of 8 percent KCl.

SUMMARY

Production and consumption of all kinds of mica except sheet and punch increased in 1944. Domestic production supplied 14 percent of all receipts of the strategic grades of stained and better in 1944, compared with 11 percent in the previous year. The increase is attributed largely to the increased use of the lower grades and improvements in domestic trimming practices.

India and Brazil remain the major producers of block mica, and India is also virtually the sole source of muscovite splittings. Production declined somewhat in India and increased in Brazil in 1944. Madagascar furnished most of the phlogopite block mica for high heat requirements as well as the better grades of phlogopite splittings. Public procurement of Madagascar mica was discontinued at the end of 1944 because of decreased requirements and a favorable stock position. On December 16, 1944, the public procurement of imported mica films was curtailed, and additional films will be purchased on a special order basis.

The premium prices paid to domestic miners by the Colonial Mica Corporation effective June 1942 were not only continued through 1944 but were increased for particular grades and sizes. The number of mica mines operating in the United States in 1944 ranged from 430 to 765 per month with a yearly average of 658 compared with 613 in 1943.

Consideration was given in the early months of 1944 to discontinue immediately the Government-sponsored program for the domestic industry, but because of the inability of the armed forces to furnish accurate information on future requirements and the uncertainty of the foreign supply, the program was continued. However, by the end of the third quarter the supply and stock of strategic mica, especially the smaller sizes, reached such a point that the War Production Board felt it no longer necessary to purchase either domestic or imported green- and black-stained mica. This curtailment was instituted to eliminate the excessive handling and preparation costs entailed in preparing green- and black-stained material.

An excellent though unofficial report on the viewpoint of the United States Army, the current world's largest consumer of mica, toward the supply, uses, and conservation of mica, has recently been published.¹ The War Metallurgy Committee of the National Academy of Sciences, National Research Council, completed a series of investigations on the conservation of strategic mica and alternate materials, the means of overcoming various defects in certain types of mica, commercialization of mica-testing equipment, and mechanical production of mica splittings, which resulted in some definite advances in the production, preparation, and marketing of mica.

The accompanying table of salient statistics gives a summary of domestic production and consumption of mica during the past 5 years.

¹ Includes mica recovered from kaolin and mica schists, as follows: 1940, 9,674 tons, \$138,148; 1941, 15,583 tons, \$185,486; 1942, 20,481 tons, \$315,807; 1943, 24,113 tons, \$314,851; 1944, 22,107 tons, \$485,567.

² Revised figures.

DOMESTIC PRODUCTION

Sheet mica.—Production of sheet and punch mica reached 1,523,313 pounds valued at \$3,262,711 in 1944 compared with 3,448,199 pounds valued at \$3,228,742 in the previous year. Punch mica supplied 55 percent of the 1944 total or 835,402 pounds valued at \$147,635 com-

¹ Wayland, R. G., Mica in War: Am. Inst. Min. and Met. Eng., Techn. Pub. 1749, July 1944, 7 pp.

pared with 78 percent of the 1943 domestic production or 2,691,083 pounds valued at \$473,955.

North Carolina remained the largest producer in 1944, supplying 49 percent of the total sheet and 57 percent of the punch and circle, compared with 47 and 57 percent, respectively, in 1943.

New Hampshire and South Dakota retained their respective places as the second- and third-largest producers. However, Connecticut ranked fourth in 1944 followed by Georgia; Idaho attained sixth place, and substantial quantities were also received from Virginia, Maine, Alabama, and New Mexico.

Mica sold or used by producers in the United States, 1935-44

¹ Includes small quantities of splittings in certain years.

² 1943: Alabama, Arizona, California, Colorado, Idaho, Maine, Maryland, Massachusetts, Montana, Nevada, New Mexico, Pennsylvania, South Carolina, Texas, Virginia, and Wyoming; 1944: Alabama, Arizona, Colorado, Idaho, Maine, Massachusetts, Montana, Nevada, New Mexico, Pennsylvania, Virginia, and Wyoming.

The decrease in the quantity of sheet and punch mica produced and the increase in value are attributed to the premium prices paid by the Colonial Mica Corporation for three-quarter and full trim sheet in sizes from 1- by 1-inch and larger. Trimming to three-quarter or full trim necessarily decreases the quantity of sheet obtained per pound of mica mined, but the increase in prices gained by this trimming more than compensates for the reduced output of the finished product. The decreased output of punch reported in 1944 thus is attributed largely to the increased quantity of the smaller sizes, such as 1- by 1-inch, that were full-trimmed and therefore classed as sheet rather than punch.

Production of sheet and punch mica is not segregated into clear and stained material on Bureau of Mines schedules. However, an index of the quantities of these classes mined may be obtained from the monthly statistics of purchases of clear and stained mica as indicated on a quarterly basis for 1943 and 1944 in figure 1. The increased use of stained mica is reflected in the upswing of purchases which began during the first quarter of 1943 and reached a peak in the first quarter of 1944. Purchases of clear sheet and punch increased through the first three quarters of 1944 and began to decline in the last quarter.

FIGURE 1.—Average monthly purchases of domestic sheet mica, clear and stained, for each quarter, 1943-44

Scrap mica.—Production of scrap mica in 1944 increased to 51,727 short tons, valued at \$1,089,072 compared with 46,138 tons, valued at \$738,025 in 1943. In addition to mine and factory scrap, these figures include 22,107 tons, valued at \$485,567, obtained from washing kaolin and by milling mica schists. Comparable figures for 1943 were 24,113 tons, valued at \$314,851.

Ground mica.—Production of ground mica in 1944 reached a new all-time high of 52,713 short tons, valued at \$1,914,709, compared with 51,582 tons, valued at \$1,990,144, in 1943, the previous record year.

Although ground mica has not been considered of strategic grade, many of the current uses are connected directly with the war program. The new asphalt landing mats produced for the Army consumed large quantities of roofing-grade mica. Clean, white muscovite mica with a low iron content was used in glass-bonded insulation in radio sets. The mica for this use came largely from New England, as the iron content of North Carolina mica is too high. Large quantities were also used in cable and telephone-wire insulation and in paints for waterproofing textile fabrics for the armed forces.

The history of the scrap- and ground-mica industries over a series of years is indicated in figure 2.

FIGURE 2.—Scrap and ground mica sold in the United States, 1923–44.

TOTAL CONSUMPTION OF BLOCK AND SHEET MICA

Requirements of the armed forces for mica began to decline during the first quarter of 1944, and the downtrend continued throughout the year. Conservation Order M-101, which defines and controls the allocation of strategic mica, was amended twice during 1944. On September 16 the necessity of filing detailed applications for authorization to fabricate mica that is in plentiful supply was lifted, and on December 12 strategic mica was redefined to include only muscovite ruby block and film sizes 5½ and larger, stained and better qualities. The effective date of the latter amendment was January 1, 1945.

Domestic consumption of strategic mica in 1944, as reported by the War Production Board, was 3,728,800 pounds. Condensers, tubes,

FIGURE 3.—Block and sheet mica (cut) and splittings imported for consumption in the United States and sales of domestic sheet and punch mica, 1928-44.

and other applications required in radio and radar equipment used 65.5 percent of the total. The remainder was consumed in magnetos, spark plugs, gage glass, compass cards, diaphragms, television, and miscellaneous uses. Stocks of the strategic grades on hand December 31, 1944, were adequate for approximately 16 months' supply at the average rate of consumption during 1944.

Figure 3 summarizes graphically the situation with respect to imports and domestic production.

MICA SPLITTINGS

Consumption of splittings reached a new high of 8,816,965 pounds in 1944, an increase of 403,603 pounds over the previous record high of 8,413,362 pounds in 1943.

Stocks of muscovite and amber splittings decreased in 1944, Government stocks declined from 19,518,691 pounds on January 1 to 12,400,261 pounds on December 31, 1944, and year-end industry stocks of 3,994,977 pounds were 522,234 pounds below the corresponding figure for 1943.

The research program of the National Academy of Sciences, National Research Council, on various mechanical methods of preparing splittings showed that it does not appear economically feasible to produce splittings from individual blocks of mica with any of the machines developed so far.

The first direct Government control of the use of mica splittings was instituted on March 15, 1944, under War Production Board Conservation Order M-101-a, which limited the use of No. 5 or larger book-form muscovite splittings to the manufacture of composite or built-up mica insulation in which the mica content is limited to an average thickness of not more than 0.003-inch, including binder. As a result of this order and completion or termination of certain military programs, the stocks of these sizes have increased to a favorable level. Peak consumption of muscovite splittings was reached in the first quarter, with a decline through the second and third quarters and an upswing in the last quarter. Amber splittings also reached a peak

Consumption and stocks of mica splittings in the United States, 1940-44, by sources, as reported by the consumers

¹ Revised figure for consumption includes 26,510 pounds of domestic splittings and 55,191 pounds of Mexican splittings, valued at \$11,308 and \$48,057, respectively; stocks include 2,200 pounds of domestic splittings and 128,959 pounds of Mexican splittings, valued at \$1,009 and \$97,963, respectively.

² Consumption includes 58,350 pounds of domestic and 76,729 pounds of Mexican splittings, valued at \$23,862 and \$55,282, respectively; stocks include 3,694 pounds of domestic and 86,001 pounds of Mexican, valued at \$1,365 and \$57,632, respectively.

in the first quarter, declined in the second and third quarters, and increased through the last quarter. Grade 6 loose splittings—first-, second-, and third-quality—in 1944 constituted 79 percent of the total consumption of muscovite splittings, compared with 81 percent in 1943. The 2-percent decrease is attributed largely to a new class of No. 6 splittings—lower than third-quality, set up late in 1944. The consumption of No. 2 quality was greater than Nos. 1 and 3, and No. 1 was greater than No. 3.

The better phlogopite splittings were obtained from Madagascar. Some lower-grade splittings were obtained from Canada and Mexico, and small quantities of machine splittings were manufactured domestically from phlogopite obtained from mine dumps in Canada.

FIGURE 4.—Consumption of specified sizes and qualities of mica splittings in the United States, by quarters, July 1943 to December 1944.

India is the sole source of muscovite splittings. As the demand and supply of this type reached a favorable balance near the end of the year, the War Production Board favored revocation of Conservation Order M-101-a, but for security reasons and indeterminable supply requirements of the armed forces the order was continued. Consumption of splittings from July 1943 through December 1944 is summarized graphically upon a quarterly basis in figure 4.

BUILT-UP MICA

The consumption of built-up mica products in 1944 increased approximately 9 percent over the 1943 figure and reached a new high of 7,438,249 pounds valued at \$10,143,940. Segment plates, used largely in the form of commutator segments and cones, made up 34 percent of the total built-up mica produced. Molding plate used in the manufacture of molded commutator rings, channels, and mica tubes accounted for 24 percent of the total, "all other tape, etc.," consumed an additional 26 percent of the total. The remaining 16 percent was used in heater plate, a rigid product capable of withstanding direct contact with high heat, and flexible plate that may be readily formed to a variety of shapes without the application of heat.

*Built-up mica produced in the United States, 1943-44, by kinds of product*¹

¹ Partly estimated.

PRICES

The buying schedule for domestic mica released by the Colonial Mica Corporation on May 24, 1943, which offered a fixed price for all sizes of sheet mica from 1½ to 2 inches and up of \$5 per pound, provided the mica is three-quarter trim or better; 40 cents per pound for punch mica having a usable area less than 1½ by 2 inches; \$5 per pound for sizes 1- by 1-inch up to 2½ inches; full trimmed, was extended to December 31, 1944. On January 28, 1944, a bonus of \$1 per pound was offered for all strategic mica delivered to the Colonial Mica Corporation purchasing shops on or before June 30, 1944. Later this bonus was extended to December 31, 1944.

Some operators offered to sell large-size full-trim sheet if an appropriate price was offered. The purchase of such material was advantageous to the Government; therefore, during the period from August 7 through December 31, 1944, the Colonial Mica Corporation paid \$8 per pound for Nos. 1 and 2 quality domestic sheet mica full-trimmed 1½ by 2 inches and larger, \$6 per pound for sheets 1- by 1-inch to 1½ by 2 inches full trim, and 40 cents per pound for punch mica.

The prices for scrap mica ranged from \$17 per short ton, f. o. b. mine, in the western region to \$25 per ton in North Carolina and New England. Dry-ground mica was quoted at \$35 per ton, f. o. b. mill,

and the wet-ground product brought \$65 to \$80 per ton, f. o. b. mill. A table of average values for sheet and punch mica is not shown, because the premium prices paid by the Colonial Mica Corp. would distort the figures.

MICA SUBSTITUTES

The use of substitute or alternate materials, such as ceramics, glass, silicone resin and rubber, Lectrofilm, and paper, as well as the increased cost of mica, have contributed to the decreasing demand for sheet and punch mica. Polystyrene and a new Dupont product called Poly F 11 also have wide application in the field formerly controlled entirely by mica.

Continued research on ceramics has led to their increased use in capacitors and spark plugs. Ceramic spark plugs have largely replaced mica spark plugs in aircraft motors, except for seaplanes, where mica plugs have a greater margin of safety to the thermal shock involved when spray hits hot spark plugs as planes alight on the water. Glass capacitors have been approved by the Navy as replacement for mica capacitors, and the Army is expected to approve their use shortly. However, paper is still the chief substitute for mica in capacitors. The resin in Lectrofilm is used as an impregnant for paper radar capacitors and increases their temperature range.

Mica is still an essential component in communication and the insulation industry, but the number of places in which mica is essential in these industries has been permanently reduced.

POSTWAR OUTLOOK

It is believed that the quantity of punch and sheet mica produced by domestic mines in the postwar years will approximate the prewar level, very closely, but the dollar value may be somewhat higher. The increased value is attributed to the improvement in trimming practices developed during the war. Domestic sheet mica is now prepared largely as full-trim material in contrast to half-trim preparation before 1942. The increased price paid for full-trim material, however, will not be adequate to allow domestic producers to compete with imported material on an equal basis.

Most of the enlarged wartime production has come from already operating or reopened mines, and few new deposits of exceptional richness have been developed. No new techniques or machinery has been devised to reduce costs, and thus mining is still largely a speculative enterprise. It is believed, therefore, that with the exception of a few large mines, the postwar mica industry will exist largely as a byproduct of feldspar mining.

FOREIGN TRADE¹

Imports.—In 1944 imports of all kinds of mica totaled 7,242 short tons valued at \$7,661,484 compared with 13,759 tons valued at \$14,854,066 in 1943. Imports of all classes of mica declined except waste and scrap (duty, 25 percent), untrimmed phlogopite (1 by 2 inches), and mica cut or stamped to dimensions, which show an increase over the 1943 total. The greatest decline was in films and splittings, the receipts of which decreased from 16,900,779 pounds in 1943 to 4,091,621 pounds in 1944. The general decline in imports and

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

particularly the large decline in imports of splittings are attributed to the relatively large stock piles of mica in the United States and the belief that the European War would end in 1944. It was felt therefore that consumption requirements could be met largely from stocks, and import quotas were reduced. Further details on imports, by kinds and sources of origin, may be found in the following tables.

Mica imported for consumption in the United States in 1944, by kinds and by countries

Exports.—Exports of unmanufactured mica in 1944 increased in quantity over the previous year's total but declined in value. The quantity increase is attributed to greater exports of nonstrategic sheet and scrap to Canada and Trinidad, the latter being a new export market. The lower dollar value is due to reduced exports of sheet mica to the United Kingdom. Exports of manufactured mica of all kinds were lower in 1944 than in 1943. Details on exports by countries and kinds of mica shipped may be found in the following table.

WORLD PRODUCTION

Complete data on world production are not available at this time, but the quality of the mica mined in the major producing countries continues to improve. The following table presents available figures by countries from 1938 to 1944.

¹ In addition to the countries listed mica is also produced in Chosen, Colombia, Kenya, Uganda, U. S. R., and Uruguay, but data on production are not available.

² Exports.

³ Data not available.

⁴ Includes following quantities recovered from kaolin and schists—1938: 5,942 tons; 1939: 9,062 tons; 1940: 8,776 tons; 1941: 14,137 tons; 1942: 18,580 tons; 1943: 21,875 tons; 1944: 20,055.

⁵ Estimate.

⁶ Less than 1 ton.

⁷ January to June, inclusive.

Argentina.—The Argentine Republic in 1944, as in the previous year, was our third-largest source of strategic mica. The major part of the mica obtained from Argentina is classed as stained mica and is made up largely of No. 6 and smaller. In August 1944 the United States Government through the United States Commercial Company began public purchase from this source, but the contract was terminated June 30, 1945, in accordance with the policy of returning trade to normal channels as soon as possible.

Brazil.—Production of the better grades of mica in Brazil continued to increase through 1944, and approximately 32 percent of the United States supply of the strategic grades in 1944 came from Brazilian mines.

Canada.—Production of block mica in Canada in 1944 came from Quebec and Ontario, and mica schist was mined in British Columbia.

Muscovite mica originated almost entirely from the Purdy Mica mines in the Eau Claire district of Ontario. A conspicuous feature of the mica from the Purdy mines is the large size of the crystals or books, some of which measure 5 by 6 feet. The following production in 1944, by Provinces, was reported by the Department of Trade and Commerce, Dominion Bureau of Statistics: Quebec, 761 short tons, valued at \$159,454; Ontario, 1,747 tons, valued at \$618,021; and British Columbia, 500 tons, valued at \$10,600. The production of phlogopite mica also increased, and large quantities of phlogopite waste from the mines were exported to the United States for processing into splittings by mechanical methods.

India.—India remains the dominant world supplier of mica, although production was lower in 1944 than in the previous year. The Government of India has set up an inquiry committee to investigate the Indian mica industry. The committee will consider postwar reconstruction, labor problems, and the ultimate stabilization of the industry.

Madagascar.—Production on this island in 1944 was small. After being blockaded for 2 years, producers recently obtained gasoline and mining equipment. However, the French Government, in an effort to rehabilitate industry, raised the selling price of block mica 35 percent and splittings 25 percent. This served to reduce production because the United States and Great Britain declined to meet the new price and made no contracts for Madagascar mica in 1945.

Southern Rhodesia.—Production of muscovite mica in Southern Rhodesia has been stimulated by the increased wartime requirements of Great Britain. The Southern Rhodesia mica industry was subsidized by the Government in much the same manner as the United States domestic industry. All mica produced must be sold to Associated Insulated Products, Ltd., an African company appointed by the Government of the Colony. There are three mica fields: Lomagundi, 120 miles northwest of Salisbury; Rusambo, about 100 miles northeast of Salisbury near the Portuguese border; and Fungwe, immediately north of the Rusambo field.

The Lomagundi field is the principal producer. It is reported that the mica industry employed 2,500 men in 1944 and furnished an estimated 30 percent of the requirements of the United Kingdom for "clear" and "slightly stained" grades of mica.

SALT

SUMMARY

A peak record of 15,717,171 short tons of common salt of three types valued at \$45,989,264, produced in the United States in 1944, represented increases of 3 percent in quantity and 5 percent in value compared with the totals in 1943.

Output of rock salt increased 6 percent and salt in brine 5 percent; evaporated salt decreased 1 percent.

The chief factors contributing to the increased quantity were expanded chemical uses, augmented production of synthetic rubber, and larger quantities used in making magnesium metal, despite the drastic cut-back in this industry.

Demand could scarcely keep pace with supply, chiefly because of labor shortage. Shipments were hampered by shortages of gasoline for trucks and scarcity of freight cars. During 1944, containers such as bags, paper cartons, and shipping cartons, continued scarce. Some industrial users overcame the situation when possible by supplying their own used sacks. A price allowance of several dollars per ton was made by the sellers for salt sold in buyers' sacks from that asked for it in sellers' sacks. In some sections of the Southwest, where drought had occurred, the livestock were removed, and sales shifted to other regions.

Salient statistics of the salt industry in the United States, 1935-39 (average) and 1941-44

	1935-39 (average)	1941	1942	1943	1944
Sold or used by producers:					
Manufactured (evaporated) short tons	2,507,374	3,330,106	3,517,832	3,993,899	3,942,621

Total:					
Short tons	46,766	15,432	7,754	1,258	5,554
Value	\$111,411	\$59,235	\$29,301	\$12,750	\$32,159
Exports:					
Short tons	90,214	123,195	118,424	145,803	198,368
Value	\$521,652	\$807,925	\$892,160	\$1,173,139	\$1,620,176
Apparent consumption² short tons	8,616,767	12,612,866	13,682,614	15,069,607	15,524,357

¹ Values are f. o. b. mine or refinery and do not include cost of cooerage or containers.

² Includes salt in bags, sacks, barrels, or other packages—1942: 122 tons, \$1,200.

³ Quantity sold or used by producers plus imports minus exports.

The accompanying graph (fig. 1) illustrates the continued rise in sales of all types of salt compared with the Federal Reserve Board index for industrial production. In terms of index numbers based on percentages of the 1935-39 average output, salt in brine rose 9

FIGURE 1.—Index of salt in brine and of evaporated and rock salt compared with industrial production, 1939-44. Index of industrial production from Federal Reserve Board.

points in 1944, reaching 198, and evaporated and rock salt combined rose 3 points, whereas the index for industrial production declined 4 points to 235.

Puerto Rican producers also reported good demand for salt throughout the year, and sales depleted all stocks. Production could not keep pace, as the effects of the damage sustained by the flood caused by the hurricane of October 1943 extended into 1944. During the second quarter of 1944 heavy rains reduced the yields further. All the salt produced on the island is solar salt and is used locally.

PRODUCTION

In 1944, salt was produced in 81 plants of 53 companies operating in 13 States and Puerto Rico, compared with 83 plants of 57 companies in 1943.

Production by States.—As for years past, Michigan led in total salt produced, followed by New York, Ohio, Louisiana, Texas, Kansas, and California. The Midwest section (Kansas, Michigan, and Ohio) produced 52 percent of the national total in 1944 compared with 53 percent in 1943. Michigan and New York together produced 46 percent of the 1944 output, Michigan leading in evaporated salt and New York in rock salt.

The following chart (fig. 2) depicts the tonnages of the three categories of salt obtained from 1939 to 1944, inclusive.

Methods of manufacture.—Various methods of manufacture are employed for the salt obtained from natural and artificial brine wells, ponds, sea water, and bedded deposits that are mined. None of the basic methods were changed or modified materially in 1944. The quantities made by each method utilized are given in the accompanying table.

FIGURE 2.—Trends in the quantity of rock salt, evaporated salt, and brine (in terms of salt content) sold or used by producers in the United States, 1939-44.

Salt sold or used by producers in the United States, 1943-44, by methods of manufacture

¹ Includes a quantity of salt contained in brine for chemical use reported as evaporated salt with value as evaporated salt.

² Included under "Other States."

³ 1943: Nevada, New Mexico, and Texas; 1944: Oklahoma, Nevada, New Mexico, and Texas.

Rock salt.—Twenty operations produced rock salt in eight States. Output cannot be shown by States because of the small number of producers involved. However, rock salt is produced chiefly in New York, Louisiana, Kansas, Michigan, and Texas; and smaller quantities in California, New Mexico, and Utah. Annual totals for 1940-44 are given in the following table:

Rock salt sold by producers in the United States, 1940-44

Year	Short tons	Value	Year	Short tons	Value
1940.....	2,265,548	\$7,384,839	1943.....	3,259,138	\$11,180,584
1941.....	2,619,087	8,761,827	1944.....	3,448,238	12,225,057
1942.....	2,802,287	9,623,461			

Pressed blocks.—Twenty-one evaporated-salt plants and eight rock-salt plants supplied the output of pressed blocks reported. They were made of plain, iodized, and sulfurized salt.

Pressed-salt blocks sold by original producers of the salt in the United States, 1940-44

Year	From evaporated salt		From rock salt		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1940.....	152,267	\$1,193,237	40,171	\$282,435	192,438	\$1,475,672
1941.....	182,331	1,505,040	56,701	461,265	239,032	1,966,305
1942.....	240,354	2,228,062	67,490	569,014	307,844	2,797,076

Salt content of brine.—Twelve plants in seven States produced 8,326,312 short tons of salt in brine in 1944 or 53 percent of total salt produced.

CHANGES IN THE INDUSTRY

Several companies that ceased operations in 1943 were still idle in 1944. Others ceased operations in 1944, including The Irvine Co., Tustin, Calif., and W. F. Flowers and Dee Stockman, Erick, Okla. Ezra S. Blackmon leased the solar salt playa formerly worked by Eklund-Blackmon Salt Co., Freedom, Okla. The Potash Co. of America, Carlsbad, N. Mex., sold ground rock salt produced as a byproduct from its potash mine. The Morton Salt Co. plant at Marysville, Mich., the company's largest Midwest establishment, was inactive part of 1944 owing to a fire that destroyed the packing and shipping departments. The Morton Salt Co., through its wholly owned subsidiary, Brine Products Inc., purchased the plant of the original Union Salt Co., Cleveland, Ohio, on May 31, 1944, and subsequently changed the name of the Brine Products Co. to the Union Salt Co., taking the name of the predecessor company.

DISTRIBUTION

The only available measure of consumption by States is the record of original shipments into States by producers. Reshipments are disregarded. In the accompanying table, salt shipped to destinations

within a State in which it is produced is added to that shipped from other States.

Shipments into a State during a year may not equal the consumption during that year but over a period of years should afford a fair index of consumption. In view of the fact that, because of its nature, salt is not stored for a great length of time, the margin of difference probably is narrow.

*Distribution (shipments) of evaporated and rock salt in the United States, 1943-44

PRESENT AND POSTWAR USES

The broad uses of the three categories of salt are shown in the accompanying table. Chemical manufacture requires the largest part of total salt. It consumed all the salt of brine and about 35 percent of the dry salt produced in the United States in 1944.

Salt sold or used by producers in the United States, 1943-44, by classes and uses, in short tons

¹ Included under "Other uses."

² Includes also exports where use is not specified.

Compared with 1943, considerably increased quantities of both evaporated and rock salt were consumed in 1944 for chlorine, soap precipitant, fish curing, refrigeration, canning and preserving, other food processing, and "other" uses, and decreased quantities for hides and leather, meat packing, dairy products, livestock, highways, table and other household, water treatment, and metallurgy.

Part of the decrease in salt used for table and other household purposes is more apparent than real, as some of the salt shown under "other" uses for 1944 includes exports of salt of a type that could be used for the purposes for which table salt is sold. Table salt required packaging; none of it is sold in bulk. The scarcity of both paper and cloth containers that has been felt increasingly in the past several

years became acute in 1944, and this slowed down production appreciably of that particular type of salt in some sections of the country.

During 1944, the United States Government purchased a large quantity of salt for the Army and Navy for food and medicinal purposes, in addition to large purchases of the salt derivatives, chlorine, soda ash, and caustic soda. As in the last several years, Government purchases of the heavy chemicals reduced the supply for civilian markets. Despite shortage for nonmilitary uses that will be increasingly relieved as the war diminishes, it seems probable that total postwar consumption will fall considerably below the requirements of the past few years. Chlorine producers are concerned over future markets and have been doing a great deal of research for new outlets.

Increased production of synthetic rubber required larger quantities of salt. Exclusive of the chlorine so used, about 140,000 short tons of salt were employed in rubber manufacture in 1944, compared with 66,000 tons in 1943. Its manufacture has become an important industry. It is reported¹ that synthetic rubber is being produced at the rate of 836,000 long tons a year compared with prewar crude-rubber imports of about 600,000 tons. The future market for salt in this field will depend upon the ability of synthetic rubber to compete with the natural rubber when the latter again becomes available and to some extent also upon the method of manufacture that will be employed.

A new process for making chlorine dioxide, which, as reported,² will overcome many limitations of past methods that produced a chemically unstable product. By the new process, it is claimed, chlorine dioxide gas is easily produced and its range of uses expanded. It is stated that it has already proved to have specific value in bleaching and maturing flour, improving taste in public water supplies, and checking blue mold in citrus fruits; experiments indicate increased yield of penicillin in an atmosphere sterilized with ClO_2 .

Salt is required for chlorine, a basic ingredient of the new insecticide DDT, production of which expanded in 1944. However, except for small quantities released for agricultural and civilian experiments, all of it was produced for direct military uses and for disease control of civilians in liberated countries. According to the findings of various Government agencies, it is expected that there will be a large postwar demand for it. At least half a dozen chemical concerns are producing DDT and chloral—its intermediate—on a large commercial scale. A postwar use contemplated is as an insect spray for homes. It has been found effective in this respect when used as an ingredient in wall paint. By the end of 1944 one large company had reduced its cost 40 percent since July and another plant was producing at a rate of two and a half times the designed capacity.

Exclusive of the quantity of chlorine used for bleaching, salt used in processing textiles and in dyestuffs declined from 255,000 tons in 1943 to about 235,000 in 1944.

Further confirmation of the anticipated postwar demand for textiles, reported in the Yearbook chapter for 1943 may be found in a textile-industry forecast³ in June 1944 that after victory our

returned demobilized fighting men are expected to buy \$18,000,000 worth of clothes a month over a 3-year period. Already our civilian supplies of textiles are in great need of replenishment. Both sodium and chlorine are necessary ingredients of dyestuffs, and salt is also used to set the colors and to exhaust the dye. Salt also performs other functions in textile manufacture, such as shrinking the material.

Salt is one of the basic materials for ingredients used in rendering fabrics resistant to fire, water, and mildew. A huge yardage of textiles for the armed forces was treated with such coatings in 1944. Early in the war mildew was said to have destroyed one-fifth of all fabrics shipped to the South Pacific. Producers of the coatings developed are looking toward broader civilian application when the war terminates.

Compounds of salt are used in making rayon, which is attaining wider fields of use, although in 1944 it was applied chiefly to war purposes, and civilian use was curtailed.

Thousands of tons of salt were used in 1944 for the production of chlorine in the manufacture of magnesium metal, a slight increase being noted despite curtailment of manufacture. The effect of the decrease doubtless will be more noticeable in 1945. However, producers that supplied salt for this purpose report that other outlets are developing.

Recently the Government confirmed the announcement that the Stauffer Chemical Co. would take over operation of the chlorine and caustic soda plant of Basic Magnesium, Inc., at Las Vegas, Nev.

Following the Government's relaxation of magnesium controls in midyear, producers planned civilian applications and marketing methods for magnesium metal. However, although widespread use of the metal in peacetime commercial and consumer products was predicted, Dr. Willard H. Dow estimated ⁴ that postwar demand would be about one-tenth present capacity; annual capacity has been about 600,000,000 pounds.

On the other hand, the production of sodium metal is increasing. It was produced by two companies in 1944, and a third will go into operation about the middle of 1945. Each ton of sodium produced takes about 2½ tons of salt. About 50,000 tons of salt will be required in 1945 if the planned program materializes.

In addition to the foregoing salt uses, a great variety of others were reported to the Bureau of Mines in 1944, such as its application in ceramics, refractories, oil refining, tobacco, glass, automotive industry, laundry and dry cleaning, coal and coke, brick and tile, pulp and paper, candles, and solvents.

Refrigerating machines that utilize salt are being used to supply a great deal of ice to the armed forces for use in hospitals, to cool water and soft drinks, and to refrigerate food.

Salt was employed as a fertilizer ingredient in 1944, although the total used in the United States is not known. According to a recent report,⁵ a greater use of agricultural salt has alleviated considerably the shortage of potash in the United Kingdom during the war years. It is estimated that a threefold increase has occurred in the consump-

⁴ Chemical and Engineering News, The Future of Magnesium: Vol. 23, Mar. 25, 1945, p. 553.

⁵ Chemical and Engineering News, World Wide Chemistry, United Kingdom, Fertilizers: Vol. 23, Jan. 25, 1945, p. 186.

tion of salt for the purpose in the past 3 years, and the demand for the coming season was expected to be great.

The fact that the United States, despite great exchange of population and overcrowded conditions, has not experienced any serious epidemics that are associated with impure water and unsanitary waste disposal is credited⁶ to the efficient use of chlorine by sanitary engineers.

Another new outlet for a salt compound is a unique process, recently devised, that employs a caustic soda bath to recover aluminum from airplanes, resulting in a high-grade aluminum that may be reprocessed into different forms. As it has been demonstrated to be a decided advance over other methods of recovery of aluminum from unsegregated scrap metals the future of this use for caustic soda appears to be assured.

Many salt mines found by the American and Soviet Armies had been utilized by the Germans as underground factories for making war materials. The most spectacular use of salt mines in 1944, disclosed recently, was the storage by the Germans of millions of dollars worth of gold and treasured works of art; the most notable was that discovered by American soldiers at Merkers.

In reverting to peacetime business, the salt industry will not be confronted with direct problems of a physical or mechanical nature in regard to its mines and plants; its principal problem will be to readjust its distributing mechanism to the changing markets. When the United States entered actively into the war, it was not necessary for salt producers and manufacturers of chemicals—especially heavy chemicals—to change equipment, processes, and procedures; they merely speeded their output and in some instances enlarged their capacity. Many salt plants did not even require capacity expansion because the existing capacity had not been fully used for some years. In the decade 1930–39, it was believed that only about two-thirds of plant capacity was being utilized. Bureau of Mines studies in recent years show that, with much the same equipment, in 1942 rock-salt mines operated at 54 percent and evaporated plants at 80 percent of capacity; in 1943, with some increases in both capacity and production, it was 62 percent of capacity for mines and 76 percent for plants; in 1944, with still further increases in both, it was 64 percent for mines and 53 percent for plants.

Although direct reconversion is unnecessary, both salt and chemical industries will be affected indirectly by cessation of the war inasmuch as numerous industries that use their basic products will have reconversion problems that will involve delay.

On the other hand, certain salt-consuming plants may be converted with little or no delay and with no substantial change in the quantity of salt employed. For instance, a magnesium-metal plant employing chlorine has changed over to metallic sodium manufacture with little modification in equipment or basic process.

Many observers foresee radical economic and industrial changes. It is inevitable that some prewar activities will never be revived and that new adaptations to peacetime, learned during the production for war, will be made, but the salt industry as a whole, except for the

⁶ Industrial and Engineering Chemistry, ind. ed., vol. 36, November 1944, p. 8, in the interpretive digest of chemical industries reports.

transition period of the salt-consuming industries, appears to be in as favorable a position as any of the essential industries and in better position than many. During World War I, great advances were made in the chemical industry in the United States, and additional gains have been made in World War II. During the interwar period the chemical industry never lost the foothold it had obtained in the First World War, and the salt output used for chemical manufacture steadily gained and did not fall below that of prewar years, except for one year: in 1921 it was less than in 1913 and 1914. During the interwar years the United States led in world production of chemicals. There is every reason to believe that, in the coming period, although some lines of business may recede the chemical industry will retain a great part of its wartime gains, and consumption of salt—one of the most important chemical raw materials—will likewise be maintained at a high level.

IMPORTS AND EXPORTS ¹

For a long time exports and imports of salt have been relatively small—hovering around 1 percent of domestic production—the imports having been consistently smaller than the exports.

¹ Less than 1 ton.

WORLD PRODUCTION

Reports to the Bureau of Mines contain information on salt in foreign countries in 1944, including: Argentina's control of its salt exports; Brazil's decree regarding duty-free salt, a plan to develop new salt wells near Aracaju, State of Sergipe, to establish a sodium chemical products industry employing the Solvay process, and another to develop a soda-ash and caustic soda industry utilizing salt from sea water at Cabo Frio, as soon as machinery can be obtained; Canada's utilization of salt in making certain heavy chemicals, hoping to retain in the postwar period a large part of its gains made in the chemical industry during the war; Chile's salt exports (in 1944, it planned

a future salt and chemical industry); China's salt production in three northwest Provinces; Colombia's salt resources and plans for developing a salt industry; Guatemala's decree dissolving the salt producers' pool; Mexico's salt deposits brought under the general mining law and Federal concessions now granted for production of salt as with other minerals; and Peru's salt deposits and industry.

Government restrictions on publication of statistics for many foreign countries have been relaxed, and the following table supplies figures heretofore lacking for several years past:

SUMMARY

Demand for magnesite for use in basic refractories was high in 1944, although slightly less than in 1943. Reduction in output of magnesium metal closed the magnesite flotation unit of Basic Magnesium, Inc., at Gabbs, Nev., late in 1944, which contributed heavily to the 26-percent drop in production of uncalcined magnesite in 1944 as compared with 1943. Mineral sources other than magnesite that provided magnesia were sea water, well brines, brucite, and dolomite. On the whole, salines showed improvement. Sales of natural calcium chloride, used mostly in road stabilization, increased slightly. Iodine output, however, was lower, owing to accumulation of Chilean stocks in this country. Antiknock requirements for military motor fuels continued active and necessitated a greater output of bromine to make ethylene dibromide. Despite accumulating stocks and labor shortages in certain areas, production of natural sodium sulfate increased 5 percent. West-coast demand for sodium carbonates in cleansers, glass, and metallurgy increased also. Sales of sodium borates, stimulated by increased demands in glassmaking, likewise were higher in 1944.

Part I.—MAGNESIUM COMPOUNDS

MAGNESITE

Magnesite production was higher in 1944 than during any year except 1943. The substantial decline from the high level of 1943 resulted from the closing of the Basic Magnesium, Inc., magnesite flotation plant at Gabbs, Nev., late in the year, owing to cut-backs in the magnesium-metal program. Labor shortages forced a virtual shut-down of the Western mine of Westvaco Chlorine Products Corp., near Livermore, Calif.; this mine supplies a dense grade of brick-making periclase difficult to procure elsewhere. On the other hand, Northwest Magnesite Co., at Chewelah opened another quarry for the production of maintenance and brick-making grades of magnesia. Re-

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

fractory demands were heavy, though less than in 1943. Caustic-calcined magnesite declined in demand somewhat, probably owing to reduced use in marine oxychloride cement flooring. Requirements of caustic-calcined magnesia for use in fertilizers, epsom salt, and rubber remained high.

The use of basic ramming mixes continued at high levels in 1944. The relative merits of a furnace lining built up from dead-burned magnesite, a layer at a time, and a furnace lining of a rammed magnesia grain are still to be decided, but wartime practice definitely favors rammed bottoms, owing to the speed with which they can be installed.

Rapid repair methods have been refined further so that shut-downs between heats are minimized. "Gun repair" has achieved considerable success; this method has been defined as "the forceful emplacement by compressed air of suitably compounded and moistened basic refractory through a hot furnace and on to the hot wall or structure to be repaired."²

Schoenlaub³ and Nicholas⁴ described the use of gun mixtures some as follows: The mix may be applied at temperatures up to about 2,200° F., and it is recommended that application follow the addition of scrap; the fuel supply may be maintained in the furnace, and no furnace time is lost. Two types of guns are used—one that adds water at the nozzle to a dry feed, and another that uses a slurry feed. Various refractories may be used, such as magnesite, chrome-dolomite, and forsterite, but there are certain requisites to be observed in for-

² Schoenlaub, R. A., Gunmix: Proc., Open Hearth Conf., Am. Inst. Min. and Met. Eng., vol. 27, 1944, p. 326.³ Schoenlaub, R. A., Work cited in footnote 2, p. 326.⁴ Nicholas, I. A., Gun Mixtures: Proc., Open Hearth Conf., Am. Inst. Min. and Met. Eng., vol. 27, 1944, pp. 331-332.

mulating the mix. The material must be very adhesive when wet, so that it will not bounce from the furnace wall, even when the wall is smooth. The refractory must not be disrupted by the steam generated as it passes through the furnace atmosphere and when it strikes the hot wall. The refractory must withstand a high temperature and must, of course, remain attached during subsequent service subject to normal wear.

Experiments with basic roofs continue, the goal being a roof that will permit higher furnace temperatures with consequent lower fuel consumption and faster steel making. Heuer⁶ points out other advantages:

The elimination of all silica brick above the floor line of the furnace will effect substantial reduction in the amount of silica that must be taken out of the furnace in the slag. This will cause reduction in the slag-making materials that must be added. Substantial reduction in the amount of maintenance materials for the walls and banks of the furnace should also result.

The temperature required to maintain a low-carbon steel for pouring is about 2,880° F., and the temperature at which silica brick in contact with iron oxide begins to soften is about 3,000° F. Commercial magnesia brick are available that will withstand 3,400° F. Despite this temperature advantage over silica brick, the latter are used in the roofs and parts of the walls of the standard open hearth, because silica brick is stronger under load, does not undergo excessive volume change with change in temperature, as does magnesia brick, and is more resistant to FeO than magnesia. Also, magnesia brick spalls notoriously with fluctuating temperatures, particularly below 2,000° F., whereas silica is little affected by temperature changes above 1,200° F.

In installing a basic roof, it is immediately obvious that the sprung arch used with silica roofs will be useless with magnesia brick, for magnesia brick cannot support loads at steel-making temperatures. A suspended roof with expansion joints has been recommended. Construction of a basic roof using burned and unburned brick has been described by Frank.⁶ After about 100 heats, the unburned brick was found to have spalled considerably, whereas the burned brick showed no spalling. It was planned to replace the spalling unburned brick with burned brick.

Magnesium oxychloride cement unjustly gained an unsavory reputation in the 1920's when attempts were made to use it in exterior stuccos without knowledge of how it should be applied. The rains came, and many poorly formulated stuccos had to be replaced. Since that time, interest in oxychloride cements has gradually recovered, and contractors are using plastic magnesia with a better knowledge of its limitations as well as its valuable flooring properties. Graf⁷ has described modern usage, and his discussion is summarized as follows:

Oxychloride cement floors may be laid over old or new floors or subbases. The floors are permanent, warm, quiet, resilient, dustproof, relatively nonslip, incombustible, inhibiting to bacteria and fungi, and have good wearing qualities. Because of its inherent resilience, magnesium oxychloride may be applied monolithically to large areas without cracking, provided there is no excessive structural

⁷ Graf, D., Plastic Magnesium Oxychloride Flooring: Pencil Points, vol. 25, No. 9, September 1944, pp. 91-92.

movement, or to smaller areas if strains are present. This property has led to its widespread use in ships and street, railway, and subway cars, where the vibration and racking impose serious demands. The material is furnished to the site of application in two parts. The first consists of magnesium oxide, aggregates, colors, and fillers which have been mixed in dry form by the installer. The second is magnesium chloride, which is furnished in flake form and is reduced to a liquid on the job by the addition of water to the required specific gravity. These are mixed into a mortar which is spread, leveled, and finished by troweling or grinding. The cost of $\frac{1}{4}$ -inch flooring may be as low as 25 cents a square foot. Costs increase with freight rates, use of special ingredients, small installations, and other factors.

On July 1, 1944, the Oxychloride Cement Association was formed, with offices at 1010 Vermont Avenue NW., Washington 5, D. C., representing Dow Chemical Co. (supplier of magnesium chloride), Westvaco Chlorine Products Corp. (supplier of lump caustic-calcined magnesia), and F. E. Schundler & Co. (grinder of the magnesia supplied by Westvaco).

PRICES

Prices of magnesite and calcined magnesia were virtually the same in 1944 as in the previous year. Very little crude magnesite is sold on the open market, and prices, which ranged from \$10 to \$15 a short ton in 1944, depend to a considerable degree on negotiation. Dead-burned grain magnesite, as sold by Northwest Magnesite Co., remained at \$22 a short ton f. o. b. Chewelah, Wash. There has been very little fluctuation in the price since 1928. Prices for the mined and synthetic magnesias of Westvaco Chlorine Products Corp. were unchanged in 1944, except that prices for mined periclase were nominal when this commodity was taken off the market later in the year. Following is a price schedule of representative magnesias sold by this firm in 1944 (carlots, f. o. b. California): Caustic-calcined magnesite, bulk—\$52.75, powdered—\$58.75; calcined (sea-water) magnesia, bulk—\$54, powdered—\$60; mined periclase, bulk, 85 percent—\$38.24, 90 percent—\$40.50; sea-water periclase, bulk, 85 percent—\$36.00, 90 percent—\$36.50.

REVIEW BY STATES

California.—Johns-Manville Products Corp., 22 East Fortieth Street, New York 16, N. Y., produced 85-percent magnesia insulation from purchased magnesite at its Redwood City (Calif.) plant. Marine Magnesium Products Corp., South San Francisco, Calif., the pioneer producer of magnesia from sea water, continued its output of high-grade magnesium oxides and hydroxide in 1944. Permanente Cement Co., Permanente, Calif., had no output of calcined magnesite in 1944 but sold small quantities from inventory. Permanente Metals Corp., Permanente, Calif., operated its Moss Landing (Calif.) plant at near capacity levels, recovering magnesium oxide from raw sea water and dolomite for use in making magnesium metal and refractories and for other purposes. Plant Rubber & Asbestos Works, 537 Brannan Street, San Francisco, Calif., produced 85-percent magnesia insulation from its plants at Emeryville and Redwood City, Calif., using purchased magnesium hydroxide and magnesite as raw materials in the respective plants. Westvaco Chlorine Products Corp., Newark, Calif., closed its Western magnesite mine at Livermore in the latter part of the year except to supply a little raw magnesite to manufacturers of magnesia insulation; the firm operated its Bald Eagle magnesite mine at Gustine, Calif., and recovered magnesium oxide from sea-

water bitterns at Newark for use in making periclase, in oxychloride cement, as a rubber catalyst, as a fertilizer, in epsom salts, and in various specialty uses.

Georgia.—International Minerals & Chemical Corp., 20 North Wacker Drive, Chicago 6, Ill., recovered magnesium sulfate from serpentine at its Augusta (Ga.) plant for use in fertilizers, tanning, and making rayon.

Illinois.—Johns-Manville Products Corp., 22 East Fortieth Street, New York 16, N. Y., produced 85-percent magnesite from dolomite at its Waukegan (Ill.) plant.

Louisiana.—Mathieson Alkali Works, Inc., 60 East Forty-second Street, New York 17, N. Y., recovered magnesium chloride from dolomite and ammonia-soda waste liquors at a Defense Plant Corporation installation at Lake Charles, La. The plant was shut down early in 1944 owing to reduced requirements for magnesium metal.

Michigan.—Dow Chemical Co. recovered magnesium chloride and epsom salt from well brines at Midland, Mich. Dow Magnesium Corp., Midland, Mich., recovered magnesium chloride from rich well brines at Ludington, Mich., for conversion to metal at the Marysville plant of the Defense Plant Corporation. Michigan Chemical Co., St. Louis, Mich., produced caustic-calcined magnesite from dolomite and well brines largely for use in the fertilizer, rayon, and rubber industries. Morton Salt Co., 310 South Michigan Avenue, Chicago, Ill., produced precipitated magnesium carbonate at Manistee, Mich., largely for coating salt grains.

Nevada.—The largest single producer of magnesite in the country—Basic Magnesium, Inc.—banked its furnaces October 1, 1944, owing to cut-backs in magnesium-metal requirements. This mammoth venture has provided much technical information, some of which appeared in print in 1944.⁸ Basic Refractories, Inc., 845 Hanna Building, Cleveland 15, Ohio, mined brucite at Gabbs, Nev., for shipment to Maple Grove, Ohio, where it is made into well-known proprietary basic refractories, including ramming mixes, surfacers, and specialties. Sierra Magnesite Co., owned jointly by Westvaco Chlorine Products Corp. and Henry J. Kaiser and affiliates, continued production at Gabbs, Nev., in 1944.

New Jersey.—Johns-Manville Products Corp., 22 East Fortieth Street, New York 16, N. Y., produced 85-percent magnesite insulation from dolomite at its Manville (N. J.) plant. The Cape May (N. J.) plant of Northwest Magnesite Co., 1800 Farmers Bank Building, Pittsburgh, Pa., recovered magnesite from sea water continuously in 1944 for use in basic refractories.

New Mexico.—International Minerals & Chemical Corp., Carlsbad, N. Mex., recovered byproduct magnesium chloride from its potash operations for conversion to metal at Austin, Tex.

Ohio.—Diamond Alkali Co., Oliver Building, 535 Smithfield Street, Pittsburgh, Pa., made magnesium chloride from dolomite at Paines-

Weinig, A. J., assr. to Basic Magnesium, Inc., of the following United States patents issued Nov. 21, 1944: Treatment of Magnesite Ores, No. 2,363,029; Flotation of Magnesite, No. 2,363,030; Froth Flotation Treatment of Low Grade Magnesite Ores, No. 2,363,031; and Magnesite Ore Treatment, No. 2,363,104, Nov. 21, 1944.

ville, Ohio, for conversion to magnesium metal. The process has been described by Avery and Evans.⁹

Pennsylvania.—Ehret Magnesia Manufacturing Co., Valley Forge, Pa., produced 85-percent magnesia insulation from dolomite. General Magnesite & Magnesia Co., Venango and Balfour Streets, Philadelphia, Pa., calcined precipitated magnesium carbonate to yield a high-grade magnesia. Keasbey & Mattison Co., Butler Avenue and Maple Street, Ambler, Pa., produced 85-percent magnesia and high-grade magnesium oxide from dolomite. The Philip Carey Manufacturing Co., 1935 Easton Boulevard, Lockland 15, Cincinnati, Ohio, produced 85-percent magnesia insulation and high-grade magnesium oxide from dolomite at its Plymouth Meeting (Pa.) plant.

Texas.—Arizona Chemical Co., 30 Rockefeller Plaza, New York 20, N. Y., recovered anhydrous magnesium sulfate from well brines at O'Donnell, Tex., for use in the rayon and textile industries. Dow Magnesium Corp., Midland, Mich., recovered magnesium chloride from sea water at the Defense Plant Corporation installation at Velasco, Tex., until closed in the latter part of the year. Dow Chemical Co. operated a smaller similar plant at Freeport, Tex. Shigley has described the Velasco operation.¹⁰ Gardner and Cates, new operators who began production of magnesite at Llano, Tex., in 1943, have now installed one rotary and one vertical kiln for calcining magnesite. Most of the output is shipped to Florida for use as a citrus fertilizer. C. E. Heinz, Llano, Tex., bought the Meramec mine at Llano from Meramec Minerals, Inc., Cleveland, Ohio, and began construction of a rotary kiln. The mine was temporarily closed in 1944. International Minerals & Chemical Co., Austin, Tex., recovered magnesium chloride from dolomite until November 1, when the plant was shut down. Processes are described by Manning and Kirkpatrick¹¹ and by Engineering and Mining Journal.¹²

Washington.—The Chewelah (Wash.) plant of Northwest Magnesite Co., 1800 Farmers Bank Building, Pittsburgh 22, Pa., continued a high rate of production of crude and floated magnesite for use in basic refractories. In anticipation of postwar demands, the firm opened its Keystone deposit.¹³

West Virginia.—Standard Lime & Stone Co., 2000 First National Bank Building, Baltimore 3, Md., continued to make "Sta-set" basic refractories by leaching most of the lime content from dolomite. This firm also produced precipitated magnesium carbonate for sale and for conversion to high-grade oxide.

FOREIGN COUNTRIES

Information on foreign developments in magnesite has been meager since the outbreak of the war. The latest Minerals Yearbook table showing world production by countries appeared in the volume review-

⁹ Avery, J. M., and Evans, R. F., Production of Magnesium at Painesville, Ohio: Am. Inst. Min. and Met. Eng. Tech. Pub. 1829, April 1945, 8 pp.; Modified MgO Process: Chem. and Met. Eng., vol. 52, No. 4, April 1945, pp. 94-96.

¹³ Rock Products, vol. 48, No. 1, January 1945, p. 230.

ing 1939. During the 5-year period 1934-38 the U. S. S. R. produced about 534,000 short tons of crude magnesite annually, followed by Austria with 403,000 tons, Manchuria 233,000 tons, United States 157,000 tons, Greece 134,000 tons, and Czechoslovakia 83,000 tons.

Brazil.—Recent investigations indicate magnesite in large deposits that occupy almost the entire Eguas Ridge northwest of the town of Brumado. Tonnage in sight has been calculated at over a hundred million. Analyses range from 20 to over 47 percent MgO .

Canada.—The value of Canadian production of magnesitic dolomite and brucite granules was \$1,260,056 in 1943, compared with \$1,059,374 in 1942. Deposits of magnesitic dolomite are worked at Kilmar and Harrington East, Argenteuil County, Quebec, for use in basic refractories. Brucite is recovered from limestone matrix at Rutherglen, Ontario, and at Bryson and Wakefield in the Province of Quebec.¹⁴

Union of South Africa.—Four companies produced 13,993 short tons of calcined magnesite in 1943, compared with 18,392 tons in 1942. Exports were 3,459 tons in 1943, compared with 6,620 tons in 1942.

Venezuela.—Magnesite on Margarita Island is being mined by a Venezuelan firm, La Industria Nueva Esparta C. A., which has a capital of \$90,000 and employs 200 workmen. The company has a plant in Caracas for making plastic magnesia products such as flooring, partitions, and ceilings. Production of crude magnesite was 589 metric tons in 1943. Analysis is 95 percent $MgCO_3$, 3 SiO_2 , 0.55 Al_2O_3 and Fe_2O_3 , and 0.75 percent CaO .

POSTWAR PROSPECTS

Available information indicates that there will be a considerable excess of supply of magnesia over demand in postwar years. Acute competition anticipated in certain grades may be made still keener if magnesium-metal producers and their affiliates should convert their plants to make magnesium oxide. Without undue difficulty, most of the plants that do not use the ferrosilicon process could convert to magnesia manufacture.

Little change is anticipated in present sources of maintenance-grade magnesia, but competition is expected to be active in brick-making grades of imported dead-burned magnesite and domestic sea-water magnesia, the former being a little cheaper (perhaps \$36 a short ton at Philadelphia as against \$40 or more for sea-water magnesia) but the latter offering greater purity and better control over final product.

The following table is indicative of possible supply and demand of magnesia in postwar years. The figures of possible production from converted magnesium plants do not include 30,000 tons of magnesium equivalent, which has been estimated as maximum postwar demand for this metal.

¹⁴ Canada Department of Trade and Commerce, Dominion Bureau of Statistics, Census of Industry, Mining, Metallurgical and Chemical Branch Report on The Miscellaneous Nonmetallic Minerals in Canada, 1943 (1945), p. 10.

Estimated postwar availability and requirements of magnesia in the United States, in short tons

Grade	Estimated postwar magnesium oxide available				Estimated postwar domestic requirements of magnesia
	From established magnesium oxide producers	Imports	From idle magnesium plants if converted	Total	
Refractory:					
Maintenance.....	278,000	{ 50,000 }	346,000	703,600	{ 100,000 }

Pure grades.....	4,700			4,700	5,000
	309,300	53,000	346,000	708,300	185,000

DOLOMITE

Crushed dolomite, both raw and calcined, is used in large quantities added alone or mixed with slag in maintaining basic open-hearth furnaces. Total sales of dead-burned dolomite are given in the following table.

Dead-burned dolomite sold in and imported into the United States, 1940-44

Year	Sales		Imports ¹		Year	Sales		Imports ¹	
	Short tons	Value	Short tons	Value		Short tons	Value	Short tons	Value
1940.....	867,900	\$6,925,328			1943.....	1,276,725	\$11,243,017	739	\$22,563

1942.....	1,229,357	10,817,634	449	11,260					

¹ Reported as "Dead-burned basic refractory material."

A new idea in stabilized dolomitic refractories was proposed by Seil,¹⁵ who found that when a dolomite-serpentine clinker was calcined at 3,500° F., the clinker remaining was stable in use at lower temperatures, preferably not higher than 3,200° F. The classical method of correcting low-melting monticellite (CaO-MgO-SiO₂) in a dolomitic refractory is to add lime to form high-melting dicalcium silicate. Schoenlaub¹⁶ suggests that, instead, the lime: silica ratio may be increased by adding the proper amount of fluorspar (theoretically one-third mole fluorspar for each mole monticellite) to the refractory mix. When heated in the kiln, the mix gives off silicon tetrafluoride. A little B₂O₃ is added to prevent inversion of the dicalcium silicate so formed.

Additional information on dolomite will be found in the chapter on Stone of this volume.

OTHER MAGNESIUM COMPOUNDS

Curtailment in production of magnesium metal forced a reduction in output of magnesium chloride in 1944. Production in 1945 is expected to be a great deal lower. Small declines were noted in

¹⁵ Seil, G. E., Conditioned Refractory Material: United States Patent 2,358,107 (1944).

MAGNESIUM COMPOUNDS AND MISCELLANEOUS SALINES 1507

production of precipitated magnesium carbonate, most of which is used in making 85-percent magnesia insulation, and in output of magnesium sulfate, used as a fertilizer, in tanning, in pharmaceuticals, and in aqueous solution as a rayon coagulant. Sales of pharmaceutical-grade magnesium oxide and hydroxide were higher on account of the demand for high-grade oxide for use in synthetic-rubber catalyst.

Part II.—MISCELLANEOUS SALINES

CALCIUM CHLORIDE

Road stabilization, concrete mixing, and coal cleaning provided excellent markets for natural calcium chloride and calcium-magnesium chloride in 1944. There were 12 producers in 1944 and 11 in 1943. (The Bureau of Mines does not canvass firms that recover calcium chloride from ammonia-soda waste liquors; there were 2 such operators in 1944.)

The following firms reported production of calcium chloride (and calcium-magnesium chloride) from natural brines in 1944; California

Rock Salt Co., 2436 Hunter Street, Los Angeles 21, Calif., plant at Amboy, Calif.; J. Q. Dickinson & Co., Malden, W. Va.; Dow Chemical Co., Midland, Mich.; Hill Brothers Chemical Co., 2159 Bay Street, Los Angeles 21, Calif., plant at Amboy, Calif.; Liverpool Salt Co., Hartford, W. Va.; Michigan Chemical Corp., St. Louis, Mich.; Ohio River Salt Corp., Mason, W. Va.; Pomeroy Salt Corp., Pomeroy, Ohio, plant at Minersville, Ohio; Rademaker Chemical Corp., Eastlake, Mich.; Frank Thomas, Room 11, 374 Court Street, San Bernardino, Calif., plant near Amboy, Calif.; and Westvaco Chlorine Products Corp., 405 Lexington Avenue, New York, 17, N. Y., plants at Chula Vista, Calif., and South Charleston, W. Va.

Calcium chloride and calcium-magnesium chloride from natural brines sold by producers in the United States, 1940-44

[In terms of 75 percent (Ca, Mg) Cl₂]

1942.....	224, 527	1, 733, 169			

Calcium chloride imported for consumption in and exported from the United States, 1940-44

Year	Imports		Exports	
	Short tons	Value	Short tons	Value
1940.....			8, 907	\$194, 738
1941.....	7	\$795	20, 777	511, 366
1942.....	1, 443	18, 926	8, 336	223, 184
1943.....	8, 000	102, 080	12, 725	434, 933
1944.....	2, 761	35, 125	8, 534	253, 641

The main use of calcium chloride is in road stabilization. A small percentage of calcium chloride is worked into a dirt binder, which is then used to fill voids between road aggregates. The calcium chloride, being hygroscopic, keeps the binder sufficiently damp to prevent lateral flow of the road surface under load. In this it is aided by internal friction of the road surfacing. Calcium chloride is added directly (2 pounds per sack of cement) to concrete mixes to obtain early strength, to prevent freezing, and to provide greater strength than ordinary concrete at all ages up to 1 year and perhaps beyond. Clay surfaces of temporary airfields have been stabilized successfully with calcium chloride. Postponed roadwork and construction are expected to provide a good market for this product in postwar years.

Prices of calcium chloride, according to Oil, Paint and Drug Reporter, were the same in 1944 and 1943, as follows: Flake, 77 to 88 percent, carlots, delivered, \$18.50 to \$35 according to zone; solid, 73 to 75 percent, \$18 to \$31.50 a ton, carlots, delivered; and 40-percent solutions, \$7.50 a ton, tank cars, works.

BROMINE

Sales of bromine compounds by primary producers again increased in 1944 to establish a new record. Sales of contained bromine amounted to 102,112,462 pounds, an increase of 9 percent over 1943. The increase was due largely to expanded production of ethylene dibromide for use in gasoline antiknock compounds.

Ethyl-Dow Chemical Co., pioneer producer of bromine from sea water, completed expansions at both its Wilmington, N. C., and Freeport, Tex., plants in 1944. Dow Chemical Co., Midland, Mich., second-largest producer, recovered bromine from Michigan well brines as a byproduct of magnesium and calcium chlorides. American Potash & Chemical Corp., Trona, Calif., recovered bromine from Searles Lake, and Westvaco Chlorine Products Corp., Newark and Chula Vista, Calif., from sea-water bitterns. The following won bromine from well brines: J. Q. Dickinson & Co., Malden, W. Va.; Great Lakes Chemical Corp., Filer City, Mich.; Michigan Chemical Corp., St. Louis, Mich.; Morton Salt Co., Manistee, Mich.; Pomeroy Salt Corp., Minersville, Ohio; Rademaker Chemical Corp., Eastlake, Mich.; and Westvaco Chlorine Products Corp., South Charleston, W. Va.

Bromine and bromine in compounds sold or used by producers in the United States, 1940-44

Year	Pounds	Value	Year	Pounds	Value
1940.....	59,266,275	\$11,772,515	1943.....	94,085,937	\$19,107,065
1941.....	68,317,019	11,506,213	1944.....	102,112,462	19,712,819
1942.....	65,880,935	13,729,383			

Bromine and bromides sold by primary producers in the United States, 1943-44

	1943			1944		
	Pounds	Value	Bromine content (pounds)	Pounds	Value	Bromine content (pounds)
Elemental bromine.....	4,171,537	\$860,461	4,171,537	3,742,307	\$766,059	3,742,307
Sodium bromide.....	4,553,376	947,567	3,551,634	1,452,901	273,839	1,133,263
Potassium bromide.....	2,953,044	643,009	1,978,539	2,687,604	586,948	1,800,695
Ammonium bromide.....	451,909	114,168	370,565	438,953	111,910	350,941
Other, including ethylene dibromide.....	99,074,044	16,541,860	84,013,662	112,281,833	17,974,063	95,076,256
	111,203,910	19,107,065	94,085,937	120,803,598	19,712,819	102,112,462

The largest use of bromine is in ethylene dibromide, which combines with the antiknock agent tetraethyl lead to form lead bromide. Lead in this form is not corrosive to spark points. Minor uses of bromine are in organic syntheses, in tear gas (bromobenzyl cyanide) as a chemical reagent, and in photographic emulsions. According to Oil, Paint and Drug Reporter, potassium and sodium bromides, U. S. P., granular, 500-pound barrels, works, were quoted at \$0.25 a pound in 1944. Bottled elemental bromine in cases, carlots, works, was quoted at \$0.21 a pound.

The bromine industry will undoubtedly be maintained at high levels in postwar years, as it is keyed directly to the sale of auto gasoline. Declines in the demand for fuels for military purposes should be offset by an increase in requirements for highway motor transport.

IODINE

There have been only two producers of iodine in the years 1937-44. In 1937, latest year for which figures may be shown, production was 299,286 pounds valued at \$242,422. Recent output, which is much higher than in 1937, is obtained from waste waters of oil wells near Los Angeles, Calif.; by Dow Chemical Co., Midland, Mich. (plant at Seal Beach, Calif.); and by Deepwater Chemical Co., Ltd., Victoria Avenue, Compton, Calif. Production decreased somewhat in 1944, compared with 1943, owing to large inventories in warehouses of the Chile Nitrate Sales Corp. (sales agent for producers of iodine from caliche in Chile).

Iodine is used as a disinfectant, in photographic emulsions, in organic syntheses, and in foodstuffs in iodine-deficient areas.

The price of crude iodine has been frozen by the Office of Price Administration at \$1.28½ per pound since 1942. Resublimed iodine in 5-pound bottles sold at \$2 to \$2.10 a pound during 1944.

The domestic iodine industry was well established before the war and has been a potent factor in reducing the price of Chilean iodine from \$4 in 1931 to as low as \$0.90 in 1936. In postwar years domestic iodine should retain at least the share of the market it had before the war.

Crude iodine imported for consumption in the United States, 1940-44

SODIUM SULFATES AND CARBONATES

Sales of natural sodium sulfates were maintained at high levels in 1944 and sales of natural sodium carbonates established a new record, despite a general labor shortage.

The American Potash & Chemical Corp. increased its output of soda ash and desiccated sodium sulfate from its expanded facilities at Trona, Calif., using the brines of Searles Lake. The Arizona Chemical Co., 30 Rockefeller Plaza, New York City, continued its production of desiccated sodium sulfate from well brines at O'Donnell and Brownfield, Tex., for the sulfate pulp market. The Desert Chemical Co., 4031 Goodwin Avenue, Los Angeles 26, Calif., shipped desiccated sodium sulfate from stocks produced at its Dale Lake plant near Twentynine Palms, Calif. The Iowa Soda Products Co., Council Bluffs, Iowa (plant at Rawlins, Wyo.), continued its production of Glauber's salt for stock feed. The Natural Soda Products Co., 405 Montgomery Street, San Francisco, recovered sodium carbonate at Keeler, Calif., from the brines of Owens Lake, Inyo County.

The Ozark Chemical Co., Mid-Continent Building, Tulsa, Okla., recovered sodium sulfate at its Monahans (Tex.) plant, largely for sale to sulfate pulp mills. W. E. Pratt, Casper, Wyo., mined Glauber's salt near Casper for stock feed. Pacific Alkali Co., 1223 Pacific Mutual Building, Los Angeles 14, Calif., produced soda ash and trona from the brines of Owens Lake; the firm was purchased on December 1, 1944, by Pittsburgh Plate Glass Co., Columbia Chemical Division, 1223 Pacific Mutual Building, Los Angeles 14, Calif., which continued production. West End Chemical Co., 608 Latham Square Building, Oakland 12, Calif., increased its production of sodium carbonate from Searles Lake. Nearly all the producers were affected by a severe labor shortage, and maintenance of production at such high levels was a real achievement.

Sodium sulfate is used principally in the manufacture of kraft paper, glass, in stock feeds, and as a flux in metallurgy. Sodium carbonate is used on the Pacific Coast mostly in glassmaking and in alkali cleansers. The prognosis for active markets for natural sodium compounds after the war remains good, owing to cost and freight advantages. For example, light soda ash made by the ammonia-soda process at Corpus Christi, Tex., sells at \$18 a short ton, f. o. b. Corpus Christi, whereas soda ash can be laid down in Los Angeles by western producers at \$18 to \$19 a short ton.

Natural sodium sulfates and sodium carbonates sold or used by producers in the United States, 1940-44

Year	Sodium sulfates ¹		Sodium carbonates ¹	
	Short tons	Value	Short tons	Value
1940.....	184,571	\$1,528,633	130,034	\$1,629,283
1941.....	154,327	1,443,137	146,677	1,822,986
1942.....	169,870	1,669,983	150,619	2,145,289
1943.....	160,622	1,553,649	165,993	2,544,086
1944.....	168,923	1,577,982	184,826	2,869,243

¹ Tonnage figures for sulfates include Glauber's salt converted to 100 percent Na₂SO₄ basis. In earlier chapters of this series the figures given for sulfates include those for Glauber's salt not so converted and were as follows—1940: 187,233 tons; 1941: 157,524 tons; 1942: 175,033 tons; and 1943: 165,908 tons. Figures for 1940-42 include some burkeite.

² 1940-41: Soda ash, bicarbonate, and trona; 1942-44: Soda ash and trona.

Domestic salt cake was quoted at \$15 a short ton, bulk, works; anhydrous sodium sulfate at \$1.70 to \$1.90 per hundredweight, works; and Glauber's salt at \$1.05 to \$1.25 per hundredweight in 1944, according to Oil, Paint and Drug Reporter. Soda ash, calcined sodium carbonate, was sold at \$0.90 to \$3.25 a hundredweight, depending on grade and other factors. Prices were the same as in 1943.

Production data for sodium carbonate produced by the ammonia-soda process for the last 4 years, according to the Bureau of the Census, are: 1941, 3,606,826 short tons; 1942, 3,788,583; 1943, 4,407,618; and 1944, 4,538,398 tons. There are no official consumption figures for sodium carbonate, but the following table, published in Chemical and Metallurgical Engineering, may be indicative.

Estimated consumption of sodium carbonate in the United States, 1940-44, by industries, in short tons¹

Industry	1940	1941	1942	1943	1944

McCarthy and associates in the Bureau of Mines published papers on the extraction of potassium carbonate from wyomingite by digestion with sodium carbonate, which may be obtained from trona.¹⁷

Sodium metal.—There were two producers of sodium metal in 1944—E. I. duPont de Nemours & Co., Inc., Wilmington, Del., and Ethyl Gasoline Corporation, 405 Lexington Avenue, New York City. Production data may not be published. The former firm sells sodium for such uses as organic syntheses, alloys, and metallurgical scavenger; the latter producer consumes its output in making tetraethyl lead, the gasoline antiknock. Metallic sodium has been under allocation (M-300-16) since November 15, 1943, to assure adequate supplies for the manufacture of tetraethyl lead. Ragno reviewed industrial uses of sodium.¹⁸

The price of sodium metal in 1944 was 15 cents a pound in blocks, carlots, works.

BORATES

Expanded exports and increased use in the manufacture of glass and fertilizer accounted for the highest boron-mineral production since 1941. Sales of contained B_2O_3 were 91,700 short tons in compounds valued at \$6,579,587, a quantity increase of 5 percent over 1943.

American Potash & Chemical Corp., 122 East Forty-second Street, New York City, continued its extraction of borax, dehydrated borax, and boric acid from the brines of Searles Lake at Trona, Calif. Pacific Alkali Co., 1223 Pacific Mutual Building, Los Angeles, Calif., recovered borax from Owens Lake at Bartlett, Calif.; this firm was purchased by Columbia Chemical Division, Pittsburgh Plate Glass Co., 1223 Pacific Mutual Building, Los Angeles, on December 1, 1944, at which time a labor shortage prevented further production of borax in 1944.

McCarthy, C. E., and Ervin, Guy, Jr., Separation of Sulfate and Chloride from Alkali Carbonate Brines: Ind. and Eng. Chem., ind. edit., vol. 36, No. 5, May 1944, pp. 415-420.

McCarthy, C. E., and Meyer, E. G., Removal of Dissolved Silica from Alkali Carbonate Brines: Ind. and Eng. Chem., ind. edit., vol. 36, No. 5, May 1944, pp. 420-422.

¹⁸ Ragno, M., Chim. ind. agr. biol., vol. 18, pp. 358-361 (1942); Chem. Zentr., vol. 1943, I, p. 1920; Chem. Abs., vol. 38, No. 16, Aug. 20, 1944, p. 4389.

Pacific Coast Borax Co. increased its production of kernite and tincal from its mines at Boron, Calif., for use in over 200 boron derivatives; the firm is expanding its plant in anticipation of heavy post-war demand. United States Borax Co., 510 West Sixth Street, Los Angeles, mined colemanite (crude calcium borate) near Shoshone, Inyo County, Calif., for refining by another producer.

West End Chemical Co., 608 Latham Square Building, Oakland, Calif., recovered borax and dehydrated borax from Searles Lake at its Westend plant.

American Potash & Chemical Corp. and Pacific Coast Borax Co. were indicted September 14, 1944, for an alleged conspiracy to restrain interstate commerce in boron compounds. The United States Department of Justice filed a civil complaint against the same defendants on the same date in the United States District Court for the Northern District of California, Southern Division.

The price of technical borax, granular, bulk, freight allowed, remained at \$41.50 a short ton throughout 1944, as in 1943 and 1942, according to Oil, Paint and Drug Reporter.

The main use of boron compounds at present is in glass. Other uses are in water treatment, soaps, medicines, ferrous alloys, flame-resisting paints, and fertilizers. Before the war, the main use was in enamels, but this market has been negligible as the result of the shortage of steel for making enamelware. Interest in boron fertilizers is increasing. Kernite concentrates, borax, and boric acid are used on boron-deficient soils to prevent corky pit in apples, heart rot and crown rot in sugar beets, brown heart in turnips and swedes, and cracked stems in celery, and to promote the growth of citrus trees, alfalfa, and cotton. The Pacific Coast Borax Co. recently revised its publication "Boron in Agriculture," which indicates the advantages of boron-fertilization.

The United States continues to be the world's main source of boron minerals, and producers have every expectation that reconversion in the United States and abroad will afford a demand at least equal to that of prewar years.

JEWELRY INDUSTRY IN 1944

The sales value of taxable jewelry in 1944 reached a record total of approximately \$1,063,000,000, 7 percent above the previous high of \$998,094,416 set in 1943. The gain is attributed principally to increases in prices rather than to a larger volume. Sales were unusually heavy during the first quarter, but from April to August they fell below the corresponding months in 1943, owing to an increase in the excise tax to 20 percent on April 1 and the belief, then current, that the war would end soon. The public had become accustomed to the new tax by September, and for the last 4 months of the year sales exceeded those of the corresponding months of 1943. Christmas shopping, which began as early as September because so many were overseas, also exceeded that of 1943. Diamonds, Swiss watches, rings, and gold-plated silver-based jewelry were the leading items. Medium-price articles sold best, although some very expensive items were purchased, probably as a hedge against inflation.

Taxes on jewelry in 1944 were \$152,765,380, an increase of 53.6 percent over those of 1943, due largely to the higher tax rate.

Prices rose somewhat in 1944 but on the whole probably less than those of good clothes or other comparable commodities.

The prosperity of the jewelry trade was based upon a record national income (161 billion dollars, compared with 147.9 billion in 1943), a large number of weddings, much cash in the hands of the average citizen, and subnormal competition for the American spending dollar.

Sales by wholesalers were somewhat less than those of 1943, and, owing to a shortage of labor and restrictions on the use of certain metals, their stocks decreased in 1944. The resale of old jewelry bolstered retailers' volume.

The retailers increasingly feel the competition by the department stores, and the sales of the latter show greater increases than those

of the retailer. A number of department stores conduct a brokerage business in used jewelry, said to be profitable. Upstairs distributors and door-to-door solicitors also compete with the sale of medium-price items, the bread and butter of the retailer.

The Canadian retailer had a good year, as did his South African and Australian confreres, although each was plagued by a shortage of stocks. By the purchase and resale of old jewelry, a vestige of life is kept in the British trade.

Costume jewelry is now a big business, sales running into several tens of million dollars a year. Base metals, silver, glass, ceramics, plastics, and a host of other materials are used, and prices of individual items have skyrocketed.

POSTWAR PROSPECTS

As to the postwar outlook, competition within the retail trade will be keen, but for a time the jewelry trade will have an advantage, for its reconversion should be rapid. One encouraging factor is that during the war many Americans have repressed a desire to spend money on beautiful things. However, if in the postwar period a substantial reduction in the national income occurs, the jewelry trade will be more adversely affected than trades dispensing food, clothes, and other necessities. With the re-entry of the European cutters into the market, gem cutters in the United States, South Africa, and Palestine will have keener competition. Some of the war-born cutting centers are likely to shrink in size or disappear. Although the consumption of industrial diamonds may decrease for a time, their expanding use in drill bits and wire-drawing dies indicates that the industrial market will be well-maintained.

FASHIONS IN JEWELS

Diamonds always show to best advantage when set in white metal. Until the war is over, palladium serves as a reasonable substitute for platinum, but thereafter platinum, without much doubt, will be the mounting par excellence for fine gems. Gold, often in two or three tones, was used, particularly in mounting colored stones; silver for the less precious stones. Even ultrafashionable jewelers began mounting garnets and other less costly but effective gems with diamonds, rubies, and sapphires. Flower designs (sometimes mounted on springs), ribbons often tied in bowknots, butterflies, and tiny animals were popular, and Victorian jewelry sprang into popularity. Egyptian motifs in necklaces are effective. Multiple-use jewelry and single-gem ensembles, clips and pins worn on coats, gowns, and hats, bracelets, earrings, and rings remained popular, whereas choker collars and hair ornaments were innovations. Stones of tremendous size are worn in rings, bracelets, and pendants. The double-ring ceremony now predominates at weddings, the service husband desiring a tangible link with his far-off wife; even double engagement rings are now used, the groom-to-be wearing a seal or crest ring.

Melee (small diamonds) to mount fine gems continued to be in short supply and expensive and were replaced in part by cabochon rubies and sapphires. Diamond, ruby, and sapphire (multicolored sapphires continued their vogue) led in popularity, followed by

topaz (true and citrine), aquamarine, emerald, and amethyst. Many other stones were worn, and the peridot is deservedly gaining popularity.

The ever-insistent demand for diamonds caused colorless, then blue and red, stones to be dominant, followed by yellow, green, and purple stones.

DOMESTIC PRODUCTION

In 1944, the value of uncut stones from domestic sources used in jewelry and related industries approximated \$41,000, which is substantially lower than the \$67,000 and \$150,000 reported in 1943 and 1942, respectively. The professional gem miner sought strategic minerals; the amateur collector did not have gasoline or tires to pursue his hobby, and the tourist (the principal purchaser of domestic gem stones) was almost nonexistent. The western lapidaries, professional and amateur, largely cut stock collected in a happier day. A few gem stones were byproducts of the intensive search for mica in the New England States.

As producers, the leading States ranked as follows: Arizona, Wyoming, Colorado, Washington, Montana, and Oregon.

Turquoise was the leading gem produced, its value having been about \$17,000. Miami, Ariz., is a new locality. The Castle Dome Copper Co., Inc., states that in its open pit "occasional specimens of turquoise are uncovered during routine mining operations. Occurrence is in the form of small veinlets. Although of sufficient hardness for gem purposes, most of this material is of a very pale-green or blue color, requiring impregnation with oil to darken the stones before they are of commercial value." Presumably, the better stones are collected and perhaps sold by the miners.

W. P. King and two miners worked the King mine, 11 miles southeast of Manassa, Colo., for about 3 months in 1944. He estimates the value of the finished product at \$7,000. The Hall and Ashcroft turquoise properties in Colorado were not operated. Apparently, the mine near Beowawe, Nev., did not operate in 1944, nor did Los Cerrillos in New Mexico. The Navajo and Pueblo silversmiths look to Colorado, Arizona, and other States for the turquoise used in their jewelry.

Agates, jaspers, and related quartz minerals probably were next in importance. Most of them are obtained in Washington and Oregon. Other producers were Montana (moss agates), Arizona (agatized wood and chalcedony), Idaho, Colorado (agates), South Dakota (agates), and Wyoming (Sweetwater moss agates). Scotts Rose Quartz Co., Custer, S. Dak., sold a little rose quartz for jewelry use and larger quantities of lower-grade material for rock gardens.

Bert A. Rhoades reports that 3,000 to 4,000 pounds of jade (nephrite) were mined in the Lander, Wyo., field. He and Byford Foster ran small cutting shops continuously and readily sold all they could cut. Three other cutters worked part time. Fred Abernathy sank a pit on nephrite in place, but the nephrite so far found is partly altered. In the summer of 1944 rough nephrite was being sold at \$1 to \$10 a pound. Some of the green jade is of good quality, and the black makes a good material for objets d'art.

Chinese agents purchased 5,890 pounds of Wyoming jade during the year to be shipped to China after the war.

The Montana sapphire industry had a poor year. Virtually all this sapphire is used industrially, only a small percentage being set in jewelry. The Perry-Schroeder Mining Co. of Helena, Mont., operated during only the first 4½ months of 1944. It produced about 4,500 ounces of culled sapphire containing \$200 to \$300 worth of gem material. No other Montana sapphire mine operated.

Alfred M. Buranek reports that the Clay Canyon, Utah, variscite deposit was worked for a short time in 1944, and that some good nodular variscite was shipped to the East. Smaller amounts were recovered from the Grantsville (Tooele County) and Lucin (Box Elder County) deposits. He estimates the value of the 1944 Utah production at approximately \$2,000. He adds that Japanese internees collected some topaz from Topaz Mountain; that a little fine malachite and azurite were obtained from the Dixie Apex mine near St. George; and that other gem stones collected in the State included "snowflake obsidian" (Black Creek), jet (southeastern Utah), and agate and chalcedony. Chalcedony was also found near Fruita, Mesa County, Colo.

Dr. Stuart A. Northrop reports that some fine green smithsonite was produced in the Magdalena district, Socorro County, N. Mex.

Other gem stones produced in the United States in 1944 were transparent albite (Newry, Maine), amethyst (Stow, Maine), aquamarine (Newry, Maine; New Hampshire; North Carolina; and Virginia), caesium beryl (Maine), garnet (Arizona), golden beryl (Maine), obsidian (Arizona), peridot (Arizona), white topaz (Maine), and colored tourmaline (Rumford, Maine).

In 1944, John Adair published a scholarly ethnologic study of American Indian silversmiths, entitled "The Navajo and Pueblo Silversmiths."

CANADIAN GEM STONES

Apparently there was no gem-stone production in Canada in 1944.

A. W. Jolliffe, of the Canadian Geological Survey, writes that in the Yellowknife Beaulieu pegmatites, Northwest Territories, small crystals of blue-green tourmaline are common; larger ones occur, but they are usually of poorer quality; red tourmaline is less common; and deep blue lazulite, possibly of gem grade, also occurs. He reports that sapphire is found in quartz at Outpost Islands, Great Slave Lake; cordierite, in the same region; fine chiastolite at Quyta Lake, 20 miles north of Yellowknife, and translucent brownish to mauve-pink andalusite in quartz bodies cutting aluminous sediments.

ACCESSIONS TO MUSEUMS

Dr. E. P. Henderson, of the United States National Museum, reports that a cat's-eye emerald of 4.56 carats was added to the Roebling collection in 1944. The chatoyant band is well-developed, and the color of the emerald is a good green. He adds that a new mineral, brazilianite, from Brazil, a hydrous sodium-aluminum phosphate, has gem possibilities; and Dr. Frederick H. Pough, of the American Museum of Natural History (New York), reports that he has two gems, each of about 20 carats, cut from brazilianite. They are slightly green-yellow in color and very brilliant.

A number of rock-crystal seals belonging to former Emperors of China have recently been placed on exhibition in the Philadelphia Museum of Art. They and many other examples of Chinese art were given to the museum by Major General and Mrs. William Crozier of Washington.

IMPORTS ¹

The value of imports of precious and semiprecious (real and imitation) stones, exclusive of industrial diamonds, totaled \$77,529,806, 8 percent more than in 1943. The value of imports of rough diamonds, emeralds, pearls, and "other precious and semiprecious stones" increased, whereas that of cut but unset diamonds decreased.

Precious and semiprecious stones (exclusive of industrial diamonds) imported for consumption in the United States, 1943-44

GOVERNMENT REGULATIONS

In January 1944, the use of gold and palladium in the manufacture of jewelry was liberalized, and on August 14, 1944, all restrictions were removed by the War Production Board, the two metals no longer being in short supply. The restrictions against copper interliners in gold-plated and gold-filled stock were almost simultaneously modified. Iridium was released from allocation on July 21, 1944, although the conservation provisions of the allocation order remained in force. The supply of this metal has been increased. No release of restrictions on the use of platinum can be expected for some time, as military and essential requirements for the metal remain large.

The War Production Board virtually prohibited the sale after March 1, 1945, of any jewelry containing tin.

Although brass may be used for silver-plated flatware, no nickel is available for production of nickel-silver. As the silver trade must depend entirely on newly mined silver, the production of silverware in the United States is small today.

¹ Figures on imports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Government regulations for control of the jewelry industry are not confined to the United States. As of October 15, 1944, the Japanese Munitions Ministry required that all platinum in the hands of its citizens be sold to the Government, indicating the severe shortage of that important war metal in Japan.

Late in October, Sweden further restricted the importation of gold, platinum, and other valuables, presumably to prevent the Nazis from using Sweden as a haven for their ill-gained wealth.

On August 1, 1944, Canada permitted the importation of jewelry from the United States. However, taxes of one sort or another are so high that it is unlikely that the trade can be large. On September 11, 1944, Canada permitted free production of jewelry and silverware, except that of items in which tin or platinum is used. Price control continues.

EFFECT OF WAR UPON THE GEM-STONE TRADE

Aerial bombing and artillery fire have doubtless destroyed some of the fine, historical, ecclesiastical jewelry of Europe; for example, that of St. Gennaro, patron of Naples, said to have been sent for safekeeping to the Monte Cassino monastery.

In October, the State Department announced that that department and Great Britain had asked neutral countries to deny protection for the Nazi loot, including jewelry. Some of the latter is in safe-deposit boxes in neutral countries under non-German names.

The war industries have borrowed from the jewelry trade methods of precision casting, both the "lost wax" and plaster-of-paris methods.

Although colored stones, especially ruby and sapphire, and many of the lesser gem stones have never been more popular, most of the world's colored-stone mines (except those of Brazil) are shut down. Consequently, many of the colored stones used today in jewelry are coming from stocks or from old jewelry. The restricted supply accounts for the rise in prices.

With the fall of the Vichy Government, the diamond production of French Guiana, perhaps totaling 20,000 carats a year, fell into the hands of the United Nations.

As the year ended, the Mogok ruby mines, heavily bombed in December, were still in the hands of the Japanese, but the Burmese jade and amber mines had been regained by the United Nations. The Mogok ruby mines apparently were won early in March 1945.

Of course, the gem mines of Thailand and Indochina were still in enemy hands. The shortage of fine cultured pearls, Japan-grown, is reflected in higher prices.

The Chinese, having been until recently cut off from one of their principal sources of jade (Burma), are investing in fine jade, the stock of which is depleted.

Our boys in the Armed Forces in India and Ceylon have purchased cultured pearls, synthetic gem stones, and glass imitations as real gems. The swindle is usually first detected when the "gems" are appraised by the American customs authorities or by some organization like the Gemological Institute of America. Similar tricks are age-old in the Orient, and even the expert is on his guard when buying gems in the East.

On the other hand, some of our men overseas make worthwhile purchases, and the star sapphires, emeralds, and cameos they acquire may well be valuable heirlooms generations hence.

DIAMOND

Although 1944, the sixth year of World War II, was not quite as good a year in the diamond industry as 1943, under the circumstances, it was much better than might have been expected. The demand for both industrial and gem stones was excellent.

Production expanded owing largely to greater production of bort from the BCK mines and of gem stones from South Africa. West African output (Gold Coast and Sierra Leone) also may have been larger. Stocks continued to decrease, consumption again exceeding production, particularly of industrial grades.

Diamond cutting appeared stabilized at about 11,000 artisans, enough to satisfy the world demand for "virgin" cut, supplemented, as it was, by well-cut stones from old jewelry.

The price of gem stones (both rough and cut) increased, but in the early fall, when some foresaw the immediate reopening of the Belgian cutting shops, the price of small cut slumped badly. By the end of the year, however, the loss had been overcome. The price of industrial stones remained stable.

Share dealings.—The shares of diamond-mining companies, virtually all of which are listed on the London Stock Exchange, registered a slight loss during the year, their performance being less satisfactory than that of the average stock on either the London or the New York exchange.

Market.—Sales in 1944 by the Diamond Trading Co., which in pre-war times sold about 95 percent of the world's production, were somewhat over £17,000,000 worth of rough, compared with £20,400,000 in 1943, the record year. Sales of gem stones held up better than did those of industrials. At several of the "sights," more stones could have been sold if there had been enough sorters to prepare them.

The American retail trade prospered in 1944, and diamond sales probably reached a peak, topping those of 1943 slightly. Sales of diamonds at retail have probably doubled since World War II began.

The price of fine cuttable rough continued to advance in 1944. Since 1939, small cut has tripled or quadrupled in price; fine cut stones have doubled in price, the increase in the case of larger stones being somewhat less.

Stocks of diamonds, both in the producers' and the Diamond Corporation's hands, have continued to decrease, and for some fine grades of industrials we are now dependent entirely on production.

Imports.—The total value of imports of gem diamonds in 1944 exceeded that of 1943, a gain of 16 percent in rough or uncut imports offsetting the loss of 7 percent in cut but unset diamonds. The quality of rough imports decreased somewhat, but that of cut, considering the slight increase in price in 1944, was constant in the two years.

Diamonds imported into the United States, 1943-44, by countries

1 Less than 1 carat.

Cutting.—Before 1940, about 90 percent of the world's diamonds were polished in the Low Countries—Belgium and the Netherlands. Since then the industry has been widely scattered over the world. The 11,000 artisans and apprentices (about one-third the prewar force) adequately supplied the world with cut stones, notwithstanding the fact that for perhaps 20 percent of their time they were unemployed (strikes, lockouts, and shortage of rough). The United States, Palestine, and Brazil are the current cutting centers.

World production.—Owing to the war, accurate figures as to diamond production are not available. The figures given for 1944 production in the table that follows are entirely estimates, but the grand total is probably approximately correct.

The world production of diamonds in 1944 is believed to have been valued at about \$40,000,000. The increase in caratage is due to an increase in BCK's crushing bort production of some 2,650,000 carats; to expansion of output in Sierra Leone, the Gold Coast, and the

South-West African alluvial mines; and to an appreciably larger production in the South African pipe mines. The value as well as the production was larger, because of increased pipe production. Of the total, some 80 percent was industrials and 20 percent gem stones.

Figures showing the production for 1940-44, corrected in minor details from those published in the chapter of this series for 1943, follow.

3 Cape and Transvaal, without Namaqualand, estimated at 53,210 carats.

4 250,000 to 370,000 carats.

5 1940-41: Borneo, India, New South Wales, U. S. S. R., and Venezuela (Venezuela produced, respectively, 14,525 and 29,399 carats); 1942: Borneo, India, New South Wales, Rhodesia, U. S. S. R., and Venezuela (Venezuela produced 31,570 carats); 1943: Venezuela (23,020 carats), Borneo, India, New South Wales, U. S. S. R., United States (Arkansas), and Bolivia; 1944: Venezuela (22,037.07 carats), Borneo, India, New South Wales, and U. S. S. R.

* Approximate.

Industrial diamonds.—World War II has been fought not only by cannon and other heavy munitions but by industrial diamonds, quartz plates, calcite prisms, and cathode-ray tubes. The diamond in over-alls is used in making virtually every kind of war munition, owing to the closer tolerances gained and time saved by its use.

Industrial diamonds are normally a byproduct of gem mining. However, in the carbonado mines of Bahia, Brazil, and the large BCK mines in the Belgian Congo, the gem stone is the byproduct.

Although the United Nations have at their disposal the production from about 99.9 percent of the world's diamond mines, yet, notwithstanding the increased production of industrials in 1944, at least a quarter of the stones used by them must be drawn from stocks mined before the war.

The supply situation of the United Nations is believed to be comfortable. Japan, on the other hand, is desperately attempting to confiscate gem stones for industrial use, and the Germans were using sintered-carbide-tipped tools as a substitute.

The demand for crushing bort continues at a record level. Dr. H. Whittaker emphasizes that the cheaper grades of industrials can replace the more expensive grades for most purposes at a saving in

cost. The consumer is learning to use the cheaper grades, as many of the finer grades are in short supply.

Owing to the exploration boom in the gold fields, more drilling was probably done in Canada in 1944 than ever before. The use of the diamond drill in blast-hole drilling is also expanding.

Fine, sound diamonds, some of gem grade, are used in making diamond dies. Since the war began, the United States has become self-sufficient in the production of dies, even those with small apertures.

FIGURE 1.—United States imports and average price per carat of industrial diamonds, 1919-44.

Figure 1, prepared by Herbert Backman, illustrates the tremendous increase in use and the sharp decline in average price per carat of industrial diamonds during recent years.

Imports of industrial diamonds into the United States during the past 5 years were as follows:

Industrial diamonds (glaziers', engravers', and miners') imported for consumption in the United States, 1940-44

RUBY, SAPPHIRE, AND EMERALD

The emerald mines of Colombia were not operated. The Burmese, Siamese, and Indochinese gem mines (largely sapphire and ruby) may have been operated on a small scale; they were in enemy hands. The Ceylonese mines were bled of labor by the island graphite mines. The production of gems, therefore, was small in 1944.

An unusually large star sapphire was exhibited for sale in New York early in 1945. It is said to have weighed over 800 carats in the rough; it was cut into a stone of 392½ carats.

LESSER GEMS

Dr. Frederick H. Pough, in a series of articles that appeared in the *Jewelers' Circular-Keystone* in 1944, has made an important contribution to our knowledge of the Brazilian gem stones. The articles contain valuable data on gem-stone prices received by miners in the field as well as dealers' prices at Rio; geographical and geological occurrence of the various gems; the heat-treatment of some of the gems; and the Brazilian cutting industry. At present Brazil is the largest producer of the lesser gem stones.

Up to the end of 1939, Australia had produced opals valued at £1,987,090. Incomplete returns for 1939 follow: New South Wales, £1,020; Queensland, £50 (only seven miners); South Australia (Coober Pedy field), £6,020—a total of £7,090. In 1944, it was reported that the black-opal fields were no longer operated.

The Anglo-American Corporation of South Africa and the South-West Africa Co. in 1943 formed the Kaokoveld Exploration Co. to prospect for minerals and precious stones in the Kaokoveld territory. This area, of 40,000 square miles, is in the northwestern part of South-West Africa.

Rubellite (red tourmaline) of excellent quality is reported to occur in Mozambique (Portuguese East Africa).

GENERAL CONDITIONS

Domestic consumption of nitrogen reached a new peak in 1944. In the first half of the year, as in 1943, allocations for agricultural use were increasing because of declining ordnance demands and expanding production. However, the downward trend in munitions production was revised abruptly in midyear with recognition of the need for more explosives in the coming military campaigns. As a result nitrogen deliveries to the fertilizer industry were slashed as early as August 1944, notwithstanding the fact that nitrogen was still urgently needed to meet the greatly increased food-production programs.

From midsummer on, increasing military demands reduced nitrogen supplies for 1944-45 crops, and at the end of the year it was believed that the quantity of nitrogen available to agriculture would be less than was used in the previous year. In June 1944 it had been anticipated that at least 675,000 tons of nitrogen would be obtainable for fertilizers, or about 7 percent more than the 630,000 tons used in 1943-44. In September estimates placed the possible supply at only 530,000 tons, but in November expectations had risen slightly to 576,000 tons.

The annual nitrogen capacity of the United States is about 1,450,000 tons,² of which 750,000 tons is that of Government plants and 700,000 tons that of plants belonging to private owners.

⁵ Less than 1 ton.

POSTWAR OUTLOOK

The maximum prewar consumption of nitrogen in the United States, in agriculture and industry combined, appears to have been less than 540,000 short tons a year, with upward trends in evidence in both types of use. In postwar times these upward trends may continue. Increased wartime requirements brought the agricultural consumption to 623,000 tons of nitrogen in 1943-44, and the immediate postwar demand is expected to equal this, with an industrial demand probably exceeding 150,000 tons.

Exports of chemical nitrogen in prewar years rarely reached 50,000 tons a year; and in postwar times, in view of a world overcapacitated for nitrogen production, the exports can hardly be expected to exceed that level, except possibly in the first years after the war closes.

Imports in prewar times ranged between 100,000 and 265,000 tons a year, averaging about 185,000 tons annually during the last 2 decades. They came largely from Chile, but with considerable quantities from Canada and Europe. In the postwar period imports may have a somewhat similar range, with supplies coming from the same regions, but increased quantities possibly may come from Canada, with its new large war-built synthetic nitrogen industry.

The present large nitrogen production capacity of the Government synthetic and the commercial synthetic and by-product plants in the United States developed under inflated wartime conditions, plus net imports, will greatly exceed normal peacetime demands. The question of postwar utilization of this large excess, involving both national and international conflicts, is still under consideration.¹

¹ See, for example:

U. S. Department of Agriculture Interbureau Committee on Postwar Programs, *The Utilization of Government Synthetic Ammonia Plants for Fertilizer Production*; August 1944, 7 pp., diagrams. *Operation and Disposal of Synthetic Nitrogen Plants: Discussions with the Government of Chile*, U. S. Department of State Bull., Apr. 8, 1945.

Some excess Government capacity could be used in the postwar period for the production of agricultural nitrogen and at least part of the balance kept in stand-by condition as an integral part of the military establishment of the Nation.

INORGANIC NITROGEN COMPOUNDS

NATURAL NITRATES

Domestic nitrate deposits.—There has been no recent development of or output from any of the domestic deposits of natural nitrates so far as is known. Deposits of soluble nitrate minerals are widely distributed throughout the United States, but all of the known deposits are too small and low-grade to serve as a basis for a domestic nitrate industry. Many of the deposits have been studied and described; references to the various published reports are given in the Nitrogen Compounds chapter of Minerals Yearbook, 1942 (p. 1522).

Chilean nitrate.—Large quantities of natural sodium nitrate and much smaller quantities of sodium-potassium nitrate continue to be imported from Chile under a wartime subsidy whereby the United States Government absorbs some of the increased costs. These imports in recent calendar years are shown in the accompanying tables. The shortage of ships resulting from world-wide military and naval operations has been a bottleneck in the movement of Chilean nitrate to the United States. The War Shipping Administration has indicated that the shipping situation will continue to be uncertain. However, according to the War Production Board, it established in October 1944 an A-3 shipping priority for 850,000 tons of 16-percent Chilean nitrate of soda for the year ending June 30, 1945, considerably more than the reported 597,000 tons brought in during 1943-44 fertilizer year.

Losses of nitrate by enemy action in the Second World War during movement from Chile to the United States have been small.

In the First World War Chilean nitrate was used largely in the manufacture of munitions, but in the present world war the great bulk of the imports into the United States has been for the production of food and feed.

Imported sodium nitrate is under allocation, first under Order M-62 dated February 1, 1942, which was revoked December 26, 1944, when sodium nitrate was placed under Schedule 80 (Nitrogen Compounds) of General Allocation Order M-300 of the War Production Board. Imports of Chilean nitrate have been inadequate for full agricultural requirements. Consequently little has been allotted to mixed fertilizers in recent years. Its use in the eastern United States has been restricted to direct application to the soil as side and top dressings.

According to the Revised Maximum Price Regulation 205 of June 30, 1944, the maximum delivered price at any destination was \$30 per ton in bulk, \$33 in 100-pound bags, or \$32.40 in 167- or 200-pound bags, plus the lowest carlot rail freight rate per ton on the material to such destination from the nitrate port that has the lowest carlot freight rate to such destination.

For nitrate of soda-potash (minimum nitrogen content 14 percent) the maximum delivered price at any destination was \$38 per ton in

bulk, \$41 in 100-pound bags, or \$40.40 in 167- or 200-pound bags, plus the lowest carlot rail freight as defined above.

Nitrate of soda imported from Chile is stored in warehouses in various United States ports. Most of it is shipped from these ports to fertilizer manufacturers in carlots. However, at New York City, N. Y., Camden, N. J., and Baltimore, Md., it has been customary for some fertilizer manufacturers to take delivery by truck. Maximum prices for the imported nitrate of soda loaded on trucks at warehouses in these three cities was increased 50 cents per ton, effective November 16, 1944, by the Office of Price Administration.⁴

Retail prices of agricultural sodium nitrate were covered by Second Revised Maximum Price Regulation 135, as amended July 26, 1944, superseding Revised Maximum Price Regulation 108 (Nitrogenous Fertilizer Materials), which formerly covered sales of nitrogenous fertilizer materials to consumers.

SYNTHETIC NITROGEN COMPOUNDS

General.—The general situation of the synthetic nitrogen industry in the United States in 1942 and 1943 was covered in the Nitrogen Compounds chapters in Mineral Yearbooks 1942 and 1943. The following summary presents the major developments in 1944.

Ammonia and certain other nitrogen compounds were under allocation by the War Production Board, General Preference Order M-163 covering byproduct ammonia; M-164, synthetic ammonia; M-62, sodium nitrate; and M-165, the remainder. All were in force throughout 1943 and up to December 26, 1944, when they were revoked. These compounds were then placed under General Allocation Order M-300, Schedules 79 (Synthetic Ammonia) and 80 (Nitrogen Compounds), as appendix B materials. The nitrogen compounds listed under Schedule 80 of December 26, 1944, were ammonium sulfate, sodium nitrate, ammonium nitrate (fertilizer grade), calcium cyanamide, ammonium phosphate (fertilizer grade), ammonium nitrate

⁴ Amendment 4 to Revised Maximum Price Regulation 205, Fertilizer Raw Materials, effective Nov. 16, 1944.

mixtures, mixed nitrogen solutions, B liquors, urea mixtures of 42 percent nitrogen (including "Uramon" but not including food grade urea).

On February 7, 1945, Schedule 80 was amended so as to substitute aqua ammonia (A, B, and C liquors) for B liquor.

Ammonia and its compounds.—The principal uses of ammonia have been military and agricultural. Minor quantities are consumed in industry. The surplus of ammonia above military demands, which appeared in 1943, continued into the first part of 1944 and agriculture benefited, but in the latter part of the year increased munitions requirements reduced the supply to agriculture.

Production of domestic byproduct-coke ammonia liquor (NH_3 content) was 31,665 short tons compared with 34,106 tons in 1943. Sales were 30,004 tons in 1944 as against 32,327 tons in 1943.

Ammonium sulfate, one of the principal sources of nitrogen in mixed fertilizers, is obtained solely as a manufactured product, and virtually all is used for fertilizer. Except for small quantities of synthetic origin the entire production in the United States comes from byproduct-coke operations. The byproduct output increased from 761,270 short tons in 1943 to 818,244 tons in 1944, whereas sales in 1944 were 776,962 tons compared with 774,815 tons in 1943. Stocks increased from 28,397 tons on January 1 to 69,031 tons at the end of the year.

Maximum prices of sulfate of ammonia, which were formerly governed by Maximum Price Regulation 205, are covered in the Revised Maximum Price Regulation 205 of June 30, 1944.

Ammonium nitrate was produced in both Government and private plants in 1944, and considerable quantities were imported from Canada. Production figures are not available. According to the United States Department of Agriculture, consumption in the 1943-44 fertilizer season for fertilizer purposes was approximately 300,000 tons. Curtailment of the supply for fertilizer purposes from Government nitrogen plants began in the summer of 1944, but deliveries from the Tennessee Valley Authority plant and from Canada continued. Munitions requirements were expected to preclude conversion of ammonia to ammonium nitrate for fertilizer by the Ordnance plants after November or December, leaving the Canadian plants as the principal source of supply during the remainder of the 1944-45 fertilizer year.

On February 1, 1944, distribution of ammonium nitrate being produced by the Army ordnance plants for use in the manufacture of fertilizer was placed in the hands of the Commodity Credit Corporation under an arrangement agreed upon by the War Production Board and the War Food Administration. The Commodity Credit Corporation in turn designated Associated Cooperatives, Inc., as its agent in the distribution of this material. This arrangement supersedes that in effect since November 1, 1943, under which Tennessee Valley Authority acted as distributor. According to report, a private company acts as distributor for the Canadian product.

The reduction in military needs freed large quantities of T. V. A. production for commercial distribution as fertilizer and also presented an opportunity for use of nitrogen fertilizers in test demonstrations in the program of T. V. A. and land grant colleges, according to the annual report of the T. V. A. for the year ended June 30, 1944.

Early in 1944 the price of ammonium nitrate produced by ordnance plants was established at \$50 a ton f. o. b. plant, plus freight charges from the nearest plant. In June the Associated Cooperatives, Inc., is reported to have announced 8- to 4-percent discounts from its basic price of \$50 a ton on fertilizer ammonium nitrate produced by T. V. A. and ordnance plants for June to September deliveries. Retail prices of ammonium nitrate are covered by Second Revised Maximum Price Regulations as amended July 26, 1944.

Higher maximum retail prices for a new Canadian grade of ammonium nitrate was announced by the Office of Price Administration in February 1945. In the northern and eastern sections of the country, where most of it will be used, this 33.5-percent nitrogen product will cost \$1.70 more per ton at retail than the old 32.5-percent grade. (Amendment 3 to Second Revised Maximum Price Regulation 135 as amended July 26, 1944, effective February 6, 1945.)

A detailed discussion of Canadian ammonium nitrate developments in recent years is given by MacRae,⁵ and the ammonium nitrate plant of the Welland Chemical Works, Ontario, Canada, is described in an article in Canadian Chemistry and Process Industries.⁶ The hazards in handling ammonium nitrate as a fertilizer are discussed by Davis,⁷ and the liability of fires and explosions of mixtures of ammonium nitrate and easily oxidizable substances; such as organic materials, are described by Davis and Hardesty.⁸

Sodium nitrate.—Little information is available regarding the current production or utilization of domestically produced synthetic sodium nitrate. According to the War Production Board, the output in the spring of 1944 was running at a rate of about 310,000 tons a year, but it is believed that the 1944 actual production greatly exceeded that figure.

According to the Revised Maximum Price Regulations No. 205, of June 30, 1944, of the Office of Price Administration, the maximum price that could be charged for domestically produced nitrate of soda (minimum nitrogen content, 16 percent) was \$27 per ton in bulk, \$30.05 per ton in 100-pound bags, or \$29.35 per ton in 167- or 200-pound bags, f. o. b. production point, provided that if and when this material is stored at Atlantic and Gulf nitrate ports by the seller, the maximum delivered price at any destination that may be charged shall be \$1 per ton higher than the above prices, plus certain specified freight rates. For nitrate of soda containing less than 16 units of nitrogen, the above maximum price shall be reduced at the rate of \$2 per unit.

Retail prices of agricultural sodium nitrate is covered by the Second Revised Maximum Price Regulation 135 as amended July 26, 1944.

ORGANIC MATERIALS

Because of restrictions in the use of chemical nitrogen in 1942 an increased demand for organic nitrogen-bearing fertilizers arose late in the year. To secure equitable distribution the War Food Ad-

ministration, on May 7, 1943, issued Food Production Order 12, effective May 1, 1943, banning purchase of these materials by fertilizer manufacturers without prior approval of the director of food production. On June 7, 1943, a revised food-production order, War Food Order 12, effective June 1, 1943, to July 1, 1944, was issued. This order limited the quantity of all such materials that could be used as fertilizer to 70 percent of the amount (in terms of nitrogen) acquired and used in the base period July 1, 1941, to June 30, 1942. Subsequently this percentage was raised to 80. On July 1, 1944, the War Food Administration revoked the broad general War Food Order 12 and issued in its place a restricted order, War Food Order 105, covering only edible oilseed meals or cake. Restrictions are retained on edible oilseed meals available for fertilizer because of heavy requirement for them for livestock feed. The new order also contained provisions governing the distribution for fertilizer use of edible type oilseed meals of inedible quality.

Calcium cyanamide (CaCN) is not produced in the United States, but is manufactured at Niagara Falls, Ontario, Canada, by North American Cyanamid, Ltd., at the only plant of its kind in the Western Hemisphere. It is marketed under the trade name Cyanamid. Considerable quantities are imported into the United States each year. The properties, reactions, and applications of this material are described in a recent article by Baughen.⁹ It has both agricultural and industrial uses. Formerly used almost entirely as a fertilizer, it has been supplanted to some extent by the introduction of direct methods of ammonia synthesis. However, its importance as a chemical raw material has increased.

GRAPHITE

Production and sales of domestic natural graphite decreased in 1944. The combined total of crystalline and amorphous graphite produced from domestic mines in 1944 was 5,408 short tons, compared with 9,939 tons in 1943; shipments reached 5,768 tons, valued at \$349,663, compared with 9,597 tons, valued at \$903,102, in 1943. Manufactured graphite was produced by the Acheson Graphite Division of the National Carbon Co., Inc., 30 East Forty-second Street, New York 17, N. Y., from a plant operated at Niagara Falls, N. Y. Stocks of crucible-grade graphite increased through 1944, and by the end of the year were sufficient for 15 months' supply at the current rate of consumption. On November 11, 1944, War Production Board Order M-61, controlling the allocation of graphite, was amended to remove crucible-grade graphite from the strategic class, leaving only Ceylon amorphous graphite, containing 95 percent graphitic carbon in lump or ground form, on the restricted list. The Ceylon material is used chiefly in the manufacture of batteries, and carbon brushes for electric motors in high-altitude bombers. Only the Ceylon material will meet the specifications for the type of carbon brush desired, and the total annual production of this grade—about 3,000 tons—is being divided almost equally between the United States and Great Britain.

As reported by the Graphite Branch of the War Production Board, approximately 67 tons of domestic flake, fines, and amorphous material were utilized in 1944 in the manufacture of crucibles, stoppers, sleeves, and nozzles.

In view of the favorable stock position of Madagascar flake at the end of 1944, a Government contract for 1945 was not signed, and Madagascar flake was released from public purchase at the end of the first quarter of 1945.

Under current manufacturing practice, domestic flake graphite alone may be used in the manufacture of crucibles up to Size 10 (capacity, about 25 pounds), but only 10 percent domestic flake can be used economically in large, foundry-size crucibles. The Bureau of Mines is conducting experimental work toward stabilizing the grade of the domestic material. It is hoped that with a more uniform product and refinements in crucible manufacture the quantity of domestic graphite suitable for use in crucibles will be increased.

Exports of natural graphite, 1940-44, were—1940: 1,632 short tons, valued at \$148,639; 1941: 1,723 tons, \$166,612; 1942: 4,095 tons, \$413,281; 1943: 3,010 tons, \$317,586; and 1944: 2,230 tons, \$248,257. The export market includes Mexico, United Kingdom, Argentina, Brazil, U. S. S. R., Venezuela, and the Central American countries.

The current market prices for domestic flake graphite in 1944 were as follows, in cents per pound: No. 1A, 14; No. 1, 13; No. 1B, 12; No. 2, 11; No. 3, 7; and No. 4, 5. Prices for Madagascar and Ceylon graphite in carlots, f. o. b. New York City, duty paid, in 1944 were, in cents per pound: Madagascar No. 1 Flake, 9 to 16; No. 2 Flake, 7 upward; Fines (ground) 55 to 70 percent carbon, 3 upward; Ceylon Lump, 10 to 12; Carbon Lump, 9 to 10; Chip, 7; and Dust, 4 to 5.

The postwar market for Madagascar and Ceylon material will remain steady. Requirements for Madagascar flake may be some-

what lower than the current demand, but demand for Ceylon amorphous 98-percent carbon may increase. Prices for Madagascar material are controlled by the French Government and at present are 15 to 20 percent higher than the 1943 figure. Ceylon prices are in a state of flux because of a Government investigation of graphite mining. It is believed that prices in these two islands in the postwar period will be comparable with the prewar prices. However, a definite statement cannot be made at present. The market and prices for domestic material will depend largely on the industry's willingness to improve and standardize the grade of its product.

Figures for total world production are not available. A table covering the period 1915-39 appears in Minerals Yearbook, Review of 1940 (p. 1414), and the following table includes all production figures that can be obtained for 1937-44.

⁵ April to December, inclusive.

⁶ Bureau of Mines not at liberty to publish figures.

GREENSAND

Production of greensand by three companies in New Jersey in 1944 reached 7,896 short tons and shipments totaled 4,908 tons, valued at \$505,651; four companies in 1943 produced 13,003 tons and shipped 10,056 tons, valued at \$522,124.

All shipments in 1944, as in the previous year, were of refined material, which was used in water-softening compounds and water-purification agents.

Prices for refined greensand ranged from \$45 to \$65 per ton for water-softening compounds to \$130 to \$160 per ton for water purification. The relatively high total value of sales reported in 1944 is attributed to the large percentage of the material sold as a water-purification agent.

Statistics of greensand sold or used are presented in the following table.

Greensand marl sold or used by producers in the United States, 1940-44

Year	Short tons	Value	Year	Short tons	Value

1942.....	10,110	448,440			

KYANITE, ANDALUSITE, AND DUMORTIERITE

Domestic production and imports of the kyanite-group minerals decreased in 1944. However, supplies and stocks of imported kyanite were more than adequate for current requirements. The Government stock-pile objective of 5,739 short tons of Indian kyanite was reached by February 1944.

Domestic shipments, imports, new supply, and stocks of kyanite in the United States, 1940-44

¹ Industry and Government stocks as of December 31, as reported by Miscellaneous Minerals Division, War Production Board.

² Figures not available.

³ Bureau of Mines not at liberty to publish figures.

Imports during the first half of 1944 were about 50 percent below those of the previous year, chiefly because of rail-transportation delays and lack of shipping space, but they increased considerably during the latter half of the year as transportation difficulties eased.

Some coarse-grained kyanite from East Africa was received; but, although the chemical analysis was satisfactory, the material which broke down to a fine powder when calcined did not meet requirements of the ceramic and metallurgical industries for heavy-duty refractories.

Imports of 298 short tons of sillimanite valued at \$3,511 were received from New South Wales, Australia, and 48 tons valued at \$2,699 from Canada. The Canadian material presumably consisted of sillimanite concentrates produced in Canada from ore obtained in Australia.

The total supply of Indian kyanite in 1944 was 16,563 tons. Domestic consumption was 7,945 tons, leaving stocks of 8,618 tons of which 2,879 were in the hands of the industry and 5,739 in the Government stock pile.

The demand for Indian kyanite did not increase materially in 1944 over 1943, even though War Production Board Conservation Order M-143 had been revoked. This is attributed partly to the comparatively high cost and long life of kyanite refractories.

Domestic production of refractory and low-iron glass-grade kyanite in 1944 did not meet requirements because of the complete shut-down on January 5 of the Yancey Cyanite Co. operations at Burnsville, N. C., sole producer of the low-iron material, and of equipment and manpower shortages at the Kyanite Products Corp. plant near Farmville, Va. The latter corporation, only large domestic producer of refractory-grade kyanite, was purchased in February 1945 by the Kyanite Mining Corp. of Cullen, Va. Spodumene and topaz have been used as substitutes for glass-grade kyanite.

The cost of Indian kyanite delivered at Atlantic seaports in 1944 was \$54 per short ton. Prices for domestic kyanite are controlled by the Office of Price Administration under Order MPR-327. Prices set for the Kyanite Products Corp. of 61 Broadway, New York, ranged from \$24 per short ton for raw kyanite, 35-mesh, in carlots, to \$42.50 for 325-mesh material, less than carlots, in 100-pound bags; and for calcined kyanite from \$31.50 per short ton, 35-mesh, in carlots, to \$47.50 for 325-mesh material, less than carlots, f.o.b. Cullen or Pamplin, Va.

Production of andalusite at White Mountain, Mono County, Calif., by Champion Sillimanite, Inc., Merced, Calif., decreased slightly from the 1943 level. Production of dumortierite at Oreana, Pershing County, Nev., by the same company—only domestic producer of either mineral in 1944—also decreased. This material was shipped to the parent firm, Champion Spark Plug Co., Detroit, Mich., for use in spark plug cores, and other electrical porcelains.

The Bureau of Mines is investigating the possibilities of domestic production of sillimanite from deposits in Georgia, South Carolina, New Hampshire, and Idaho. The deposits in the Southern States consist of 20 bodies of sillimanite schist ranging in width from a few feet to 200 feet, which extend in a northeasterly direction from Talbotton, Ga., to Spartanburg, S. C., and appear more promising than the deposits in the Monadnock region of New Hampshire and those near Troy, Latah County, Idaho.

The postwar demand for Indian kyanite for heavy-duty refractories will remain strong unless a domestic deposit of kyanite or sillimanite is found which contains recoverable material in grain sizes similar to the Indian material (one-quarter inch to 35-mesh) or can be agglomerated to form a grog of a consistency comparable with the Indian material. Prices should be somewhat lower than the wartime figure when shipping rates are reduced to peacetime levels.

The market for domestic kyanite may show an increase because of improvements in mining and milling technique and because of the trend toward mixing kyanite and topaz to obtain a refractory product with a high pyrometric cone rating. Prices should be steady but may be influenced by the proposed change in southern freight rates.

LITHIUM MINERALS

Domestic production of the lithium minerals and compounds—spodumene, amblygonite, lepidolite, and dilithium sodium phosphate—reached an all-time high in 1944. The chief gain in tonnage was in spodumene, the output of which increased 87 percent over the 1943 total. However, percentagewise, the largest gain was in dilithium sodium phosphate, which increased 187 percent. The output of amblygonite and lepidolite was respectively 30 and 38 percent below the previous year's total. With the exception of lepidolite for the glass-making industry, for which we depended largely on material from Southwest Africa, the 1944 output of lithium minerals was adequate for all requirements.

The Solvay Process Co. plant at Kings Mountain, N. C., although not reaching maximum output, was the major producer, followed by the Black Hills Tin Co. at Tinton, S. Dak. The latter plant, however, operated only from February through August 1944. A new lepidolite producer—the Hayden Mining Co. of Colorado Springs, Colo.—began operations on the Brown Derby Claims in Gunnison County in June 1944. The increased output of dilithium sodium phosphate is attributed to the installation of a flotation process at Searles Lake, Calif., by the American Potash & Chemical Corp. By July 1944 domestic production of spodumene and dilithium sodium phosphate had exceeded requirements, and the excess was shipped to the Government stock pile. On September 30, 1944, General Conservation Order M-253 of the War Production Board, controlling the allocation of spodumene effective December 5, 1942, was revoked. Most of the Army contracts expired December 31, 1944, and have not been renewed; as a result, the Solvay Process Co. plant at Kings Mountain ceased production temporarily in February 1945.

Shipments of lithium ores and compounds from 1940 through 1944 are shown in the following table. An approximate figure for the total Li_2O content, obtained from the average Li_2O percent of the ore reported by the producers, is also included.

Shipments of lithium ores and compounds from mines in the United States, 1940-44

Year	Ore (short tons)	Value	Li_2O (short tons)	Year	Ore (short tons)	Value	Li_2O (short tons)
1940.....	2,011	\$80,679	113	1943.....	8,155	\$314,660	463
1941.....	3,832	115,718	209	1944.....	13,319	552,977	848
1942.....	5,405	243,516	299				

Prices for lithium ores produced in the United States for sale on the open market, as quoted by E&MJ Metal and Mineral Markets in 1944 were as follows: Spodumene, \$5 to \$6 per 20 pounds of contained lithia (Li_2O), 6 percent minimum, \$30 per short ton, in carlots; amblygonite, 8 to 9 percent (Li_2O), \$40 to \$50 per short ton, f. o. b. mine; and lepidolite, 3 percent (Li_2O), \$24 to \$25 per short ton, f. o. b. mine.

By October 1944 the United Nations had succeeded in cutting off the supplies of amblygonite to Germany from Spain and Portugal. Shipments of amblygonite from Spain reached 105 metric tons in 1943 and 70 tons in January to October 1944.

Markets for lithium ores and compounds are expanding rapidly. However, because wartime restrictions on purchase of machinery have prevented the Solvay Process Co. from completing its milling unit at the Kings Mountain (N. C.) plant and because many of the postwar uses will be new, it is not possible at this time to forecast postwar prices and markets for lithium minerals.

MINERAL EARTH PIGMENTS AND MANUFACTURED IRON OXIDE PIGMENTS

[Prepared by Charles L. Harness]

Heavy demand for military uses kept several of the synthetic iron oxides in very tight supply during much of 1944, but the natural earth pigments (except ochers and natural yellows) were generally available despite a manpower shortage which closed many deposits and curtailed processing. Iron oxide pigments are now used mostly in military and essential industrial paints, but in normal times there is a substantial consumption in house and barn paints and in linoleum, mortar colors, chicken feed, and glass polishing.

Statistics of production and foreign trade are presented in the following tables.

Natural mineral pigments and manufactured iron oxide pigments sold by processors in the United States, 1943-44, by kinds

¹ Less than 1 ton.

Prices of finished earth pigments, which are quoted in cents per pound, were generally unchanged during 1944, according to the Oil, Paint, and Drug Reporter. Precipitated magnetic blacks, in barrels, less carlots, works, were quoted at 8½; metallic browns were 2½ in barrels; Vandyke brown sold at 9 (special grade at 12), and sap brown crystals at 12; synthetic (pure) browns, 12; synthetic (pure) red iron oxides, 9 to 9½; Venetian reds, 2.2 to 4, depending on iron oxide content; natural yellow oxides, high iron, 5; synthetic (pure) iron oxide yellows, 7.1; domestic French-type ochers, 3.45; burnt siennas, American type, were quoted over a range of 3½ to 5; Italian type burnt siennas, 8¼ to 10¼; raw siennas, American type, ranged from 4 to 10; raw siennas, Italian type, 8 to 10; Turkey-type umbers were quoted at 4¼ to 5¼, depending on quality and point of purchase.

After the war, according to trade reports, precipitated yellow iron oxides will continue to hold most markets formerly enjoyed by French ochers. Satisfactory replacements have been found for raw Italian ochers but not for burnt types. Likewise, umbers from the Island of Cyprus and red oxide from the Persian Gulf have not been equaled and will probably find a ready postwar market here. Although several excellent replacements for Spanish red oxide have been reported, its cheapness and relative availability have kept it in fair demand. Some domestic Vandyke brown producers expect to go out of business when cheaper German grades are again available.

MINERAL WOOL

Mineral-wool production in 1944 reached 568,296 short tons, valued at \$54,482,796, an increase of 16,772 tons in quantity and \$10,812,086 in value over 1943. Production in 1944 came from 38 companies operating 51 plants in 19 States, compared with 40 companies operating 53 plants in 19 States in 1943.

The production of both home and industrial insulation increased. The change in the industrial field is attributed to the increased requirements of the armed forces for mineral-wool insulation products on ships, aircraft, tanks, and other military equipment, and the realization by industry that complete insulation is necessary to maintain maximum efficiency and production during the war period. The large increase in dollar value is attributed to the amendment of Order A-2 of Maximum Price Regulation 188, effective from September 16, 1943, granting relief to mineral-wool manufacturers to cover increased manufacturing costs, and to the larger production of the relatively higher-cost industrial insulation. Prices in 1944, per short ton, in carlots f. o. b. plant, were \$37.50 for loose and \$53 for granulated wool, compared with \$30 and \$45, respectively, in 1943.

The postwar market for mineral-wool insulation will be strong. However, with the increased use of lightweight glass insulation more emphasis will be placed on the density per cubic foot of the finished product. Because of the bulk of most mineral-wool products, which prohibits haulage over great distances, prices are controlled largely by local conditions, and it is difficult to estimate price conditions for the industry as a whole. It is believed, however, that postwar prices for loose and granulated mineral wool, f. o. b. plant, will approximate the 1943 figures.

Production of mineral wool in the United States, 1943-44, by products

MONAZITE

Imports of monazite sand, the only commercial source of the rare-earth elements, decreased 92 percent in quantity and 94 percent in value in 1944 compared with 1943. They were obtained entirely from India. Consumption, as reported by the War Production Board, was also lower in 1944 when 1,990 short tons were processed, compared with 2,075 tons in 1943, a decline of 4 percent. The decrease in imports is attributed partly to the low shipping priority given this material and the reduction in number of ships sent to India during the year. The Government stock pile—3,262 short tons—was completed by the end of May 1944. Industry stocks decreased in 1944 but were still sufficient for more than 2 years' supply at the current rate of consumption.

Monazite is consumed in the production of ferrocenium and numerous chemical compounds. Rare-earth oxides and fluorides are used as cores in carbon-arc electrodes for searchlights, moving-picture projectors, and floodlights. Rare-earth oxides are used as a glass-polishing compound, and rare-earth hydrates and cerium hydrate are required in the manufacture of special optical glass.

The war has brought a definite change in the specifications for monazite sands. The current basis for valuing monazite sands is the rare-earth oxide content contrasted with the prewar requirement for an 8-percent thoria content in the material. Most of the new uses are directly connected with the prosecution of the war, and although many have postwar possibilities it is difficult at this time to evaluate future markets and prices.

OLIVINE

Shipments of olivine from North Carolina decreased to 3,270 short tons valued at \$35,207 in 1944, from 5,415 tons valued at \$48,633 in 1943. The entire production in both years was consumed in refractories. Prices for crude olivine, f. o. b. North Carolina, were quoted at \$5 to \$7 per short ton; ground olivine, 200-mesh, \$17, and 20-mesh to dust, \$12 per ton.

It is expected that the postwar market for olivine will remain essentially at the prewar level. Prices, which have been affected very little by the war should remain virtually at the current level. However, if the west-coast steel plants continue to operate or expand, a market for olivine in the Twin Sisters Mountain region of Washington may develop.

RADIO-GRADE QUARTZ

Domestic production of radio-grade quartz in 1944, as reported by the War Production Board, was 3,934 pounds valued at \$23,769, compared with 5,968 pounds valued at \$25,598 in 1943.

Imports of quartz crystal for use in the manufacture of piezoelectric quartz plates for radio, telephone, and detection equipment reached 2,300,506 pounds valued at \$11,178,643 in 1944, of which 1,658,000 pounds (72 percent) was of radio grade. Corresponding figures for 1943 were 3,356,000 pounds valued at \$11,409,803, of which 1,825,000 pounds (54 percent) met specifications for radio-grade material. Except for 2,156 pounds obtained from Angola, Chile, Colombia, Cuba, Ecuador, Guatemala, and Portuguese Guiana, the entire imported supply was received from Brazil. Private importers obtained 81 percent of the total imports, and the remainder was purchased by the Metals Reserve Company.

The total new supply of radio-grade quartz in the United States in 1944, therefore, was 1,661,934 pounds.

The total number of finished plates produced in 1944 reached 29,939,000 and comprised 29,766,000 radio oscillators, 153,000 telephone resonators, and 20,000 other types of plates (as reported by the Miscellaneous Minerals Division of the War Production Board). This represents an increase of 33 percent over the 1943 figure of 22,576,150 plates—22,486,200 oscillators, 65,595 telephone plates, and 24,355 other types. The average number of plates obtained per pound of usable quartz in 1944 was 17. This increase in number of

plates produced in 1944 is attributed largely to improvements in technique that have made possible the utilization of material previously rejected and to an increase from 54 to 72 percent in the ratio of radio-grade material to total quartz crystal imported.

The value of the radio-grade quartz consumed annually has reached the point where crystal production is almost too large to be called a minor-nonmetal industry. This increase has come primarily from expansion of Brazilian production and was accomplished largely by United States Government assistance in mechanizing many of the producing properties and by a price stimulation that has not been controlled by specific OPA orders. An energetic program of conservation, substitution, scrap recovery, and research, also established by the Government, late in 1942, has resulted in the discovery of the usability of large quantities of material previously considered unsatisfactory. Our consumption and stock-piling programs could not have been met without the integration of these Government programs carried out in Brazil and the United States.

The most important recent development of the research program is the X-ray method of irradiation perfected by Reeves Sound Laboratories, Inc., whereby frequencies of oscillator plates may be adjusted downward from their original values. Thus, plates overshot in frequency during manufacture or that have gone over frequency due to aging, recleaning, or underplating may be recovered provided the desired frequency change is within the range of radiation technique.

The sale of imported quartz crystals by private importers and Government agencies was brought under control of the General Maximum Price Regulation of the Office of Price Administration on July 15, 1944, by Amendment 64 to Revised Supplementary Regulation No. 1. This amendment revoked the exemption of imported commodities sold to agencies, contractors, or subcontractors of the United States or Allied Governments. The amendment provides that the Metals Reserve Co. maximum prices for quartz crystals shall be the prices set out in its current price schedule of February 18, 1944.

General Conservation Order M-146 of the War Production Board was amended during 1944 to increase the number of permitted uses of quartz crystals because of an easier supply : demand ratio. Before March 20, 1944, crystals could be used only in the manufacture of radio oscillators and filters for war purposes and a few other military items. In addition to these uses, they may now be used for radio oscillators and filters for Government activities directly connected with defense, public health, welfare, or security; for commercial broadcasting stations and communication systems; and in the manufacture of optical or electrical parts for use in research or production instruments manufactured to fill orders rated AA-2X or higher.

Because attempts at domestic production were relatively unsuccessful, the Metals Reserve Company ceased purchasing domestic material at the end of 1944.

Brazilian quartz crystal is recovered from four types of deposits: Veins, blanket replacement, pegmatites, and residual or placer. The largest percentage is obtained from vein and blanket-replacement deposits. Production comes primarily from four States: Minas Gerais, 35 percent; Goiaz, 30 percent; Bafa, 25 percent; Esperito

Santo, 5 percent; others, 5 percent. The average deposit produces about 1 ton of usable material per month, and the ratio of marketable to unmarketable quartz ranges from 1 : 3,500 in the better deposits to a low of 1 : 100,000 in the leaner mines.

Small quantities were recovered and shipped from Madagascar to England in 1944; the crystals from this island are found largely in caverns in quartzite. It is reported that a deposit of radio-grade quartz which covers 20 square kilometers was discovered in the Central Urals of Russia at Khaibullinsk in 1943; operations began in the same year.

Government buying prices established August 4, 1943, did not change during 1944. They ranged for faced quartz from \$1.95 for third-grade material weighing 0.44 to 0.66 pound to \$36.95 for first-grade material, 60 to 100 percent usable, weighing 22 pounds or above; \$1.56 to \$33.25, respectively, for unfaced quartz; and \$1.60 to \$2.40 for small material, which must be faced, weighing 0.22 to 0.44 pound. The complete table is contained in minerals Yearbook, 1943 (p. 1586).

The demand for radio-grade quartz in communication and detection devices will continue at a high rate in the postwar period. It seems probable also that the United States and the rest of the world will depend primarily on the Brazilian deposits. However, with the advances in manufacturing technique, and the expected release to the open market of a greater quantity of the larger and better-grade material, which during the war has been largely allocated to Great Britain, it is believed that adequate supplies for all countries will be available. The price structure will be controlled, at least partly, by the economic policies of the Brazilian Government, which at present is requesting equipment to process the raw materials into the finished plates. It may well be, therefore, in the postwar period, that purchasers of radio-grade quartz may be required to obtain a part of their supply in finished plates. If so, the price for radio-grade quartz will be higher than the current wartime figure.

STRONTIUM MINERALS

[Prepared by Charles L. Harness]

Requirements for celestite (natural strontium sulfate) in signal flares and tracer bullets declined sharply in 1944, and activity in the domestic industry was maintained chiefly by a demand for well-drilling weight material that could not be supplied by barite producers. Small quantities of domestic celestite were sold for the purpose of adsorbing iron from caustic-soda liquors and for making strontium chemicals.

Shipments of celestite by producers totaled 3,005 short tons valued at \$48,165 in 1944 compared with 7,566 tons valued at \$114,526 in 1943. Imports for consumption were 5,793 short tons valued at \$86,419 in 1944 compared with 16,881 tons valued at \$249,580 in 1943. Mexico was the chief supplier in both years. Consumption of all celestite in strontium chemicals amounted to about 6,000 tons in 1944 compared with 13,387 in 1943.

The following producers shipped celestite in 1944: Milwhite Co., Inc., Cotton Exchange Building, Houston, Tex., deposit near Blanket,

Brown County, Tex.; Bennett-Clark Co., Inc., Box 951, Nacogdoches, Tex., deposit in Nolan County, Tex.; Pan-Chemical Co., 205 First National Bank Building, Pomona, Calif., deposit in the Fish Mountains of Imperial County, Calif.; and W. C. Buehler and W. N. Rowe, 1555 Sunset Avenue, Pasadena, Calif., deposit near Ludlow, Calif.

The price of celestite delivered in the Philadelphia area was about \$30 in 1944, the same as in 1942 and 1943.

The domestic industry has little prospect of continued activity after the war. For high-grade uses the impure Texas celestite cannot compete with 92-percent material available in Mexico, Spain, and England. California celestite can compete in analysis but not in freight costs. The lower-grade domestic celestites are satisfactory as drilling mud, but after the war they probably will be unable to compete with celestite from England, which may be available at prices as low as \$15 a short ton ex docks Philadelphia.

TOPAZ

Production and sales of topaz in 1944, as in 1943, by the United Feldspar & Minerals Corporation of Spruce Pine, N. C., from the Brewer mine, near Kershaw, S. C., exceeded the previous year's total. Topaz was used as a substitute for fluorspar by some steel companies and has been found to be the most useful of all fluorine-bearing minerals employed in making leadless glaze, as it gives off its fluorine at a temperature somewhat under the maturing temperature of the glaze.

Tests at the Wilson Dam Laboratory of TVA on the calcination and defluorination of topaz in a rotary kiln for use as a substitute for Indian kyanite in the manufacture of high-aluminum, mullite-type refractories has produced encouraging results.²

Domestic topaz and kyanite have been used at the Bureau of Mines Electrotechnical Laboratories, Norris, Tenn., in the manufacture of a lightweight superduty brick that meets not only the A. S. T. M. shrinkage requirements in reheat tests but also the more severe Navy reheat specifications. Additional research is now in progress to prevent press cracks and warping during firing.³

A larger market for topaz may result from these and similar investigations now in progress at the Bureau of Mines and TVA laboratories and experiment stations.

³ Galbreath, W. W., McVay, T. N., and Allen, D., Lightweight Superduty Kyanite-Topaz Refractory: Jour. Am. Ceram. Soc., vol. 27, No. 8, 1944, pp. 241-246.

VERMICULITE

Sales of cleaned and screened vermiculite in 1944 increased 7,471 short tons (16 percent) above the 1943 total and approached very closely the all-time high of 57,848 tons in 1942.

The bulk of the production in 1944, as in previous years, came from the Universal Zonolite Insulation Co. mine at Libby, Mont. Several new companies carried on development in Colorado in 1944 and expected to produce early in 1945. A report on the Wyoming vermiculite deposits by Arthur F. Hagner,⁴ including information on occurrence, physical properties, specifications, and production, was released by the State geological survey in March 1944; and a review of the South African deposits, including material on preparation and uses and a flow sheet of an exfoliating plant, has been published.⁵

Fire-retardant qualities of vermiculite plaster on metal lath-wood stud partition and steel floor construction with vermiculite-plaster ceiling and vermiculite-concrete top floor were tested by Underwriters Laboratories, Inc., of 207 East Ohio Street, Chicago, Ill., in August and September 1944. Under test conditions, the vermiculite products in the two units delayed 1 and 4 hours, respectively, the spread of the flames from one portion of the building to another.

Two new agricultural uses have been reported for exfoliated vermiculite—as a seed starter in place of peat moss and as an agricultural mineral admixture that acts as a subirrigation and mulching agent, to improve garden and lawn soil.

The quantity of vermiculite consumed in refractory products and in cement continues to expand.

Production figures for domestic mines from 1940 through 1944 follow. A table covering the period 1924–39 appears in *Minerals Yearbook, 1940* (p. 1480).

Screened and cleaned vermiculite sold or used by producers in the United States, 1940–44

Year	Short tons	Value	Year	Short tons	Value
1940.....	22, 299	\$137, 698	1943.....	48, 645	\$471, 595
1941.....	23, 438	125, 444	1944.....	54, 116	541, 744
1942.....	57, 848	319, 931			

Screened vermiculite brings \$8 to \$12 a short ton, f. o. b. mine. However, most of the material reaches the consuming market in the exfoliated form. The price for exfoliated vermiculite is quoted at 70 cents to \$1.25 per bag, each bag containing 4 cubic feet weighing 25 pounds, or \$56 to \$100 a short ton, f. o. b. works. Assuming a value of \$75 a ton for exfoliated material and a 10-percent loss in volume on exfoliating, the value of sales of exfoliated material in 1944 would be approximately \$3,652,800.

⁴ Hagner, A. F., *Wyoming Vermiculite Deposits*: Wyoming Geol. Survey Bull. 34, 1944, 47 pp.

⁵ Laschinger, J. E., *Vermiculite Technology*: Min. Jour. (London), vol. 223, No. 5689, 1944, pp. 567–569, No. 5690, 1944, pp. 581–582.

Wartime conservation of fuel has not only increased the uses and value of insulating materials but also has been instrumental in lowering the weight specifications for these materials. It seems probable therefore, in view of the lighter weight of glass wool and some rock-wool insulation products, that the postwar market for exfoliated vermiculite will be largely in the field of lightweight aggregate for concrete and structural and refractory uses. Prices for cleaned and screened vermiculite have not changed materially during the war and should not fluctuate greatly in the postwar years.

WOLLASTONITE

Production and sales of wollastonite in 1944 from the Burnham property near Willsboro, N. Y., exceeded the 1943 total. In March 1945 the deposit was leased to the Titanium Alloy Manufacturing Co., 111 Broadway, New York 6, N. Y. As industrial uses for this material are expanding, an enlarged postwar market is anticipated.

PART IV. MINE SAFETY

EMPLOYMENT AND ACCIDENTS IN THE MINERAL INDUSTRIES

SUMMARY

The down trend in the number of men working in the mineral industries continued throughout 1944, and total employment for the year fell to an estimated 693,800 men, a decline of 9 percent from 1943. The falling-off in mineral industry employment intensified the acute shortage of manpower and held back production of newly mined material in some mineral industries, notably in mining of fuels and certain metals and nonmetals. Unrestricted demand for nearly all mineral products was extremely high but could not be realized because war controls permitted the meeting only of war and "essential" civilian demands and severely restricted "nonessential" civilian needs for all mineral products. In the coal-mining and byproduct-coke industries, however, demand increased in the face of a steadily dwindling number of workers, and the labor-supply problem became more and more serious through 1944. Production in the coal industry was increased only by lengthening the working day and by working more days during the year.

The total man-hours of productive work in the extractive industries, which had gained appreciably in each year since 1938, turned downward in 1944, and the yearly total of slightly more than 1½ billion man-hours was 2 percent below 1943. The time worked in 1944 was lower than in 1943 in each of the mineral industries except coal mining and byproduct-coke production. The aggregate man-days of work in the mineral industries fell 7 percent below 1943, a sharper decline than occurred in man-hours owing principally to the reduction in number of employees.

Although the war-controlled demand for some minerals was off somewhat from 1943, production had to be maintained at high levels in many mineral industries. This was accomplished with a reduced labor force by increasing the number of workdays to 285 as an average for all industries in 1944 compared with 279 in 1943. A second means of meeting requirements was to lengthen the workshift, which advanced from an average of 7.55 hours per day in 1943 for all industries to 7.94 hours per day in 1944. As a result, the average employee in the mineral industries worked 2,264 hours during 1944 compared with a corresponding total of 2,104 hours in 1943.

¹ Revised figure.

² Subject to revision.

The foregoing employment data point out the difficulties in meeting production requirements in many mineral industries and indicate some of the accumulated strains of 3 years of war on the employees who, during the past several years, have worked longer days and more days each year.

Despite these and other handicaps brought on by the war, the over-all safety record of the mineral industries for 1944, as measured by injury-frequency rates, was the best ever attained in any year since the start of complete injury statistics on mining and quarrying in 1930. The estimate of 1,563 fatalities among workers in the mineral industries in 1944 was lower than in any year since 1939 and was at a rate of 1.00 per million man-hours of exposure to hazards. The number of nonfatal injuries that disabled employees for longer than the day on which the accident occurred was estimated to be 86,391 for the year. This total was the lowest of any year since 1940 and was at a rate of 55.01 per million man-hours worked, a slight decline from the corresponding nonfatal rate of 55.73 in 1943. This record is most commendable when it is considered that such wartime handicaps as loss of skilled employees to the armed forces, relatively high rates of labor turn-over, the longer workday, maintenance of a high level of output with reduced personnel, and the difficulties in securing repair parts and replacements for badly worn machinery were surmounted successfully.

FIGURE 1.—Trends of employment and fatal and nonfatal injuries in the mineral industries of the United States, 1933-44.

The safety record in the coal-mining industry had the greatest improvement of any of the mineral industry groups in 1944 over 1943. The frequencies per million man-hours of work in coal mining during 1944 were estimated at 1.29 on fatal and 65.83 on nonfatal injuries compared with corresponding final rates of 1.56 and 69.55 in 1943. In the metal- and nonmetal-mining industries, the injury records also were more favorable than in 1943. These industries had the following preliminary rates per million man-hours of exposure in 1944: Metal mining, 0.80 on fatalities and 54.89 on nonfatalities; and nonmetal mining, 0.60 for fatalities and 51.77 for nonfatalities. The quarry, coke, and metallurgical plants had poorer safety records in 1944 than in 1943, and the estimated injury-frequency rates in these industries advanced to 0.58 for fatalities and 34.43 for nonfatalities in quarrying, to 0.21 for fatal and 26.43 for nonfatal injuries in metallurgical plants, and to 0.19 for fatalities and 14.43 for nonfatalities in coke plants.

EMPLOYMENT AND ACCIDENTS

BITUMINOUS-COAL MINES

Employment.—The principal drain on the labor supply of bituminous-coal mines in 1944 was the drafting of men into the armed forces. Other contributing elements were the attraction of employees from coal mining to less-arduous or higher-paying industries, the retirement of elderly miners, and the loss of manpower through accidents. The combination of these factors in the tight wartime labor market that prevailed through 1944 resulted in a reduction of workers in bituminous-coal mines to 380,000 men from 407,135 men in 1943. The shortage of labor was acute in all except a few scattered localities of the coal-producing areas of the country.

Despite the sharp drop in labor force, production of bituminous coal in 1944 was estimated to have advanced to the record annual total of 620,000,000 short tons. This output was attained with the available supply of labor by working more days, working more hours per day, and more intensive development of stripping operations, which have a high productivity per man employed. As a result of the first two means, the average employee in 1944 worked 8.00 hours on each of the 276 days that the mines were operated compared with 7.28 hours per day and 263 days active in 1943. Total hours of work per year by the average employee advanced markedly to 2,208 in 1944 from 1,911 man-hours in 1943. The mines were operated an estimated total of 839,000,000 man-hours in 1944, a gain of 8 percent over 1943. These data on man-hours of work exclude the "travel time" of underground employees and represent time spent at the place of work. Results of a statistical study¹ under direction of the President's Committee on Portal to Portal Travel Time revealed that a weighted average of 55.88 minutes was required each day by underground employees in bituminous-coal mines to travel from the mine portal to the working place and return to the portal.

Accidents.—The safety record in bituminous-coal mining improved in 1944, and the injury-frequency rates were lower than in 1943. An estimated total of 1,120 men was killed in accidents at the mines in

¹ Letter report to the President of the United States from President's Committee on Portal to Portal Travel Time, May 24, 1944, 2 pp., 6 tables.

1944 at a frequency of 1.33 per million man-hours of work compared with 1.58 in 1943. Nonfatal injuries were estimated to have caused 52,900 men to lose time from work in 1944. These nonfatal injuries occurred at a rate of 62.05 per million man-hours, which was a moderate reduction from the corresponding rate of 65.64 in 1943.

During 1944, there were 4 major disasters in which 94 men lost their lives—22 in explosions of gas or dust and 72 in mine fires. During 1943, there were 7 major disasters in which 161 men lost their lives—148 in explosions of gas or dust and 13 in a mine fire.

Of the 1,120 men killed at bituminous-coal mines in 1944, approximately 92 percent occurred in underground workings, 3 percent in stripping operations, and 5 percent in surface work around the mines. Slightly more than half of the fatalities occurring underground resulted from falls of roof or face, about 20 percent were haulage accidents, 4 percent were caused by machinery, and 3 percent by electricity; the remainder resulted from various other causes. Detailed information on causes of the nonfatal injuries in 1944 are not available, but experience in recent years indicates the following probable cause-distribution in order of frequency of occurrence: Falls of roof or face, haulage, handling materials, hand tools, and machinery.

ANTHRACITE MINES

Employment.—Manpower was scarce in the anthracite-producing regions of Pennsylvania throughout 1944 for reasons similar to those affecting bituminous-coal mines. Although demand exceeded production and allocation of available supplies was used to effect equitable distribution, the number of men working in the anthracite industry declined to 77,500 in 1944 from 79,381 in 1943. However, by the expedients of working the available labor force more days during the year and lengthening the shift slightly and also by increasing the production of strip and culm-bank coal, the total output of prepared anthracite was increased over 1943 to approximately 63,200,000 short tons in 1944. This tonnage excludes "bootleg" coal purchased and prepared by recognized producers, for which no employment data are available. The average employee in 1944 worked 7.17 hours on each of the 292 days the mines were active, compared with 7.05 hours per day for 269 days in 1943. The annual total of hours worked by each employee advanced to 2,090 in 1944 from 1,900 man-hours in 1943. The mines were operated an estimated total of 162,000,000 man-hours in 1944, an increase of slightly more than 11,000,000 hours over 1943. Data on the anthracite industry include underground, strip, surface, culm-bank, breaker, washery, and dredge operations.

Accidents.—An estimated total of 173 fatal injuries occurred in 1944 or 53 less than in 1943. The number of nonfatal injuries likewise was below 1943 and was estimated at 13,000 in 1944. The frequency rates per million man-hours—1.07 for fatalities and 80.25 for non-fatalities—were sharply lower than in 1943. Of the fatal injuries about 88 percent occurred underground, 5 percent in strippings, and 7 percent in surface works.

"Bootleg" operations.—"Bootleg" operations apparently are much more hazardous than the mines of recognized producing companies. Comparison of the accident records of the legitimate industry with data computed from compilations² of the Anthracite Committee

² Anthracite Committee, Seventh Survey of Bootleg Holes: Commonwealth of Pennsylvania. Dept. of Commerce, Mar. 7, 1945, 7 pp.

shows a total of about 365,000 tons of coal mined and prepared for each fatality in legitimate operations, whereas only 61,905 tons were mined in "bootleg" mines for each fatal injury in 1944. According to the committee, there were 61 fatalities in "bootleg" operations in 1941, 45 in 1942, 22 in 1943, and 21 in 1944. Output from "bootleg" mines was estimated at 6,300,000 short tons in 1941, 3,900,000 in 1942, 1,900,000 in 1943, and 1,300,000 in 1944. Men employed in "bootlegging" coal totaled 10,762 in 1941, 4,967 in 1942, 2,752 in 1943, and 2,220 in 1944.

IRON-ORE MINES

Employment.—Employment data on iron-ore underground and open-cut mining declined sharply in 1944. The number of men employed fell 12 percent from 1943 to approximately 26,200 in 1944, and the total time worked decreased 14 percent to about 59,000,000 man-hours in 1944. Employees worked an average of 281 days in 1944 and 290 in 1943.

Accidents.—Injuries occurred at virtually the same frequencies in 1944 as in 1943. Tentative figures indicate that there were 38 fatal and 1,458 nonfatal injuries in 1944 compared with 47 and 1,663 injuries, respectively, in 1943. The frequency rates in 1944 were 0.64 per million man-hours for fatalities and 24.69 for nonfatalities.

COPPER MINES

Employment.—The number of men working at underground and open-pit copper mines declined markedly to an estimated total of 18,500 in 1944 or 22 percent lower than in 1943. Total man-hours of work in the industry fell 23 percent from 1943 to approximately 46,500,000 hours in 1944. The mines were operated 309 days or 11 days less than in 1943.

Accidents.—The 1944 accident record improved moderately over 1943. Preliminary estimates indicate that 38 men were killed and 2,536 injured nonfatally during the year. Fatal injuries in 1944 occurred at a rate of 0.82 and nonfatalities at 54.46 per million man-hours. The corresponding rates were 1.15 and 57.77 in 1943.

LEAD-ZINC MINES (MISSISSIPPI VALLEY STATES)

This classification includes lead-zinc mining operations in Arkansas, Oklahoma, Missouri, Kansas, Tennessee, Illinois, and Wisconsin. In prior years, fluorspar mines in Kentucky and Illinois were included also, but they have been transferred to the nonmetal-mine group. The data for 1943 and 1942 have been revised to be comparable with 1944.

Employment.—The number of men working in this group of lead-zinc mines fell 21 percent below 1943 to a preliminary total of 7,300. The total volume of employment, measured in man-hours, declined to slightly more than 16,000,000 hours, or 19 percent lower than in 1943. However, employees worked an average of 280 days compared with 275 in 1943.

Accidents.—Accidents at these operations in 1944 resulted in 15 deaths and 1,311 disabling injuries. The fatality rate of 0.92 per million man-hours of exposure in 1944 was slightly more favorable

than in 1943 but was higher than the 0.56 rate for 1942. The frequency of nonfatal injuries was appreciably higher in 1944 and was at a rate of 80.00 compared with 60.71 in 1943 and 48.31 in 1942.

GOLD AND SILVER MINES (LODE AND PLACER)

This group includes not only mines operated principally for gold and silver but also those lead-zinc mines outside the Mississippi Valley States. After the gold mines were closed by the Federal Government as a war measure in 1942, the group in 1943 and 1944 comprised largely the lead-zinc mines in the Eastern and Western States.

Employment.—On a basis of preliminary reports, about 11,400 men worked at lode mines and 800 at placers. Lode mines in 1943 employed 14,885 men and placer mines 1,398. Man-hours of work totaled 26,300,000 at lode mines and 1,100,000 hours at placer. The lode mines were worked 294 days in 1944, an increase of 7 days over 1943, whereas placers were operated only 170 days or 10 less than in 1943.

Accidents.—Accidents at lode mines resulted in 32 fatal and 2,772 nonfatal injuries, at respective frequencies of 1.21 and 105.22 per million man-hours of exposure. The nonfatal injury rate was slightly improved over 1943, but the fatality rate was poorer. There were no fatal injuries at placer operations in either 1943 or 1944. However, the frequency of nonfatalities advanced from 32.67 in 1943 to 37.82 per million man-hours in 1944.

MISCELLANEOUS METAL MINES

Mines producing antimony, bauxite, chromite, cobalt, manganese, manganiferous iron, mercury, molybdenum, pyrite, titanium, tungsten, and vanadium-uranium are included in this group.

Employment.—Employment at operations in this classification receded sharply from 9,229 workers in 1943 to an estimated total of 5,000 men in 1944. Man-hours of work fell to approximately 10,500,000 in 1944 from nearly 21,000,000 in 1943. Similarly, the mines were operated only 262 days or 21 days less than in 1943.

Accidents.—The safety record in the miscellaneous metal mines was more favorable than in 1943. There were 5 fatal and 664 nonfatal injuries at respective rates of 0.47 and 62.88 per million man-hours of work in 1944. The corresponding rates in 1943 were 0.95 for fatalities and 68.61 for nonfatalities.

NONMETAL MINES

This group includes operations producing barite, feldspar, fluorspar, gypsum, magnesite, mica, phosphate rock, rock salt, sulfur, and other miscellaneous nonmetallic minerals. It does not include operations producing limestone, granite or other stone, sand, gravel or clay. Fluorspar mines in Kentucky and Illinois are included in this report under this classification for the first time by transferring them from Lead-zinc (Mississippi Valley States). The 1942 and 1943 data have been revised to be comparable with 1944.

Employment.—An estimated total of 11,900 men was working in the mines of this group during 1944—a decline of approximately 800

men from 1943. The aggregate man-hours worked by these men fell to approximately 26,500,000 hours in 1944 from nearly 28,000,000 in 1943. The average mine in the group was operated 255 days during the year.

Accidents.—The injury record in nonmetal mines improved over 1943. The estimated total of 16 fatal injuries was at a rate of 0.60 and the 1,372 nonfatal injuries at 51.77 per million man-hours of exposure. The corresponding rates for 1943 were 0.89 for fatalities and 52.57 for nonfatalities.

CEMENT MILLS AND QUARRIES

Employment.—Reports indicate that 20,600 men were working in cement mills and quarries, a 20-percent decrease from the 25,811 men in 1943. Man-hours of employment fell 25 percent to a total of 44,800,000 hours in 1944. The continued decline in demand for cement resulted in the plants working an average of 273 days in 1944 or 26 days less than in 1943.

Accidents.—The safety record at cement plants was not as favorable as in 1943, and the rate of fatal injuries increased slightly to 0.40 and of nonfatal injuries to 14.73 per million man-hours of exposure in 1944. There were 18 fatalities and 660 nonfatalities at cement mills and quarries in 1944.

MARBLE QUARRIES

Employment.—The decline in employment at marble quarries, which started in 1942, continued throughout 1944. Approximately 1,400 men worked 3,200,000 man-hours in 1944 compared with 1,540 men and nearly 3,700,000 hours in 1943. The quarries were active an average of 264 days in 1944.

Accidents.—The one fatal injury in 1944 was at a rate of 0.31 per million man-hours. There were 98 nonfatalities; these had a frequency of 30.63 per million man-hours of work, more favorable than the corresponding rate of 37.04 in 1943.

SLATE QUARRIES

Employment.—Although there was a slight improvement in demand, the number of workers in slate quarries decreased to 1,200 in 1944. Man-hours of employment showed little change from 1943 and totaled 2,600,000. The quarries were operated 259 days in 1944 or 10 more days than in 1943.

Accidents.—There were 3 fatal and 153 nonfatal injuries in 1944, at respective frequencies of 1.15 and 58.85 per million man-hours. These rates were markedly higher than in 1943, when there were no fatalities and the nonfatality rate was 50.07.

TRAP-ROCK QUARRIES

Employment.—The estimated 2,000 employees at trap-rock quarries worked a total of 4,100,000 hours in 1944 or moderately less than the 2,256 men working approximately 4,300,000 hours in 1943. Days of operation of the quarries increased to 241 in 1944—18 days more than in 1943.

Accidents.—A more favorable safety record was attained in 1944 than in 1943; 2 fatalities and 220 nonfatalities occurred, at rates of 0.49 and 53.66 per million man-hours. In 1943, the fatality rate was 0.93 and the nonfatality rate 58.98.

GRANITE QUARRIES

Employment.—Available reports indicate that 4,100 men worked about 9,000,000 man-hours in granite quarries during 1944. This was a decrease in both the number of men employed and man-hours worked when compared with 1943. The quarries were operated an average of 259 days in 1944 or 16 days more than in 1943.

Accidents.—Both the fatality and nonfatality rates were higher in 1944. The 6 fatal and 417 nonfatal injuries were at respective frequencies of 0.66 and 45.93 per million man-hours in 1944. The corresponding rates in 1943 were 0.52 and 41.94.

SANDSTONE QUARRIES

Employment.—The approximately 2,100 workers at sandstone quarries in 1944 were 14 percent fewer than in 1943. These men worked a total of 4,300,000 man-hours, which was 12 percent below 1943. Days of operation of the quarries increased 8 over 1943 to a total of 250 days in 1944.

Accidents.—Two fatalities and 238 nonfatalities during 1944 represented rates of 0.47 and 55.35 per million man-hours of exposure. These rates were an improvement over the fatal injury rate of 0.82 and the nonfatal injury rate of 56.82 during 1943.

LIMESTONE QUARRIES

Employment.—The number of men employed in limestone quarries declined 12 percent from 1943 to a total of 19,100 men in 1944. Approximately 39,200,000 man-hours were worked or a 13-percent drop from 1943. The number of operating days decreased 1 to a total of 241 days in 1944.

Accidents.—The estimated 27 fatalities and 1,600 nonfatalities in limestone quarries in 1944 represented frequencies of 0.69 and 40.82 per million man-hours of work. The rate of fatal injuries was unchanged, but for nonfatal injuries the rate was improved over the 42.96 frequency in 1943.

LIME PLANTS AND QUARRIES

Employment.—Available reports indicate that the 9,000 men employed in lime plants and quarries worked 23,000,000 man-hours in 1944. This represented declines of 12 percent in men and 10 percent in man-hours from 1943. Lime plants were operated the same number of days in 1944 as in 1943.

Accidents.—There were 16 fatal and 1,100 nonfatal injuries at lime plants in 1944 compared with 15 and 1,284 injuries, respectively, in 1943. The fatality rate advanced to 0.70 per million man-hours, and the nonfatality rate improved from 50.33 in 1943 to 47.83 in 1944.

BYPRODUCT-COKE OVENS

Employment.—Final employment data at byproduct-coke ovens show a total of 21,586 men working in 1944 or only slightly under 1943. Man-hours of employment increased slightly to 62,800,000 compared with 62,600,000 hours in 1943. The gain in man-hours was attained by lengthening the work-shift to 8.02 hours in 1944 from 7.98 in 1943. The coking plants were operated 363 days in both 1943 and 1944.

Accidents.—Accidents at byproduct ovens caused 12 fatalities and 752 nonfatalities which were at corresponding frequencies of 0.19 and 11.97 per million man-hours of exposure. This fatality rate was more favorable than the 0.24 frequency noted for 1943. The nonfatality rate in 1944, however, was less favorable than the 9.75 rate in 1943.

BEEHIVE-COKE OVENS

Employment.—As demand for beehive coke slumped, employment declined rapidly to an average of 3,100 men in 1944, a 25-percent decrease from 1943. These men worked an average of 260 days in 1944, compared with 265 days in 1943. Man-hours of employment totaled 6,400,000 in 1944 or 20 percent below 1943.

Accidents.—The injury record at beehive ovens improved in 1944. One fatality and 247 nonfatalities occurred during the year at frequencies of 0.16 and 38.59 per million man-hours, respectively. In 1943, the corresponding frequency rates were 0.25 for fatal and 46.72 for nonfatal injuries.

ORE-DRESSING PLANTS AND AUXILIARY WORKS

Plants or mills in this group are those in which ores of all metals are processed or treated. The types of operations included are crushing, grinding, washing, concentrating, sintering, cyaniding, leaching, Bayer process, and other methods by which ores of metals are treated. Auxiliary works associated with these mills are principally machine shops, yards, and general construction work.

Employment.—The number of men employed in 1944 ore-dressing plants totaled 23,400 of which 14,700 men worked in direct milling of ore and 8,700 men were employed on the auxiliary works. The total employment was off slightly from 1943. The volume of employment measured in man-hours also declined slightly from 1943 to a total of slightly more than 59,000,000 hours. Man-hours worked declined from 1943 in mill operations but increased at the auxiliary works. Copper, miscellaneous metal, lead-zinc, iron, and gold-silver mills ranked in that order in number of workers and man-hours of work performed in 1944.

Employment and accident data at mills and auxiliary works in the United States, 1942-44, by metals

¹ Includes crushers, grinders, washers, ore-concentration, sintering, cyaniding, leaching, Bayer, and all other metallic ore-dressing plants.

² Includes maintenance and repair shops, yards, general construction, and other associated works.

³ Includes antimony, bauxite, alumina, mercury, manganese, tungsten, chromite, vanadium, molybdenum, titanium, and other metals. Mills producing alumina included in 1943-44 but not in 1942.

Accidents.—The combined fatal and nonfatal injury rate of 26.20 per million man-hours at mills and associated works was virtually unchanged from 1943. However, injuries in mills occurred more frequently in 1944, whereas the frequency of injuries in the auxiliary works was more favorable than in 1943. Iron mills and auxiliaries had the best safety record in 1944 of the various groups of plants arranged according to ores processed.

SMELTERS, REFINERIES, REDUCTION PLANTS, AND AUXILIARY WORKS

Plants in this group are engaged in the primary extraction of non-ferrous metals from ores and include, among others, smelters, refineries, and reduction, roasting, electrolytic, and retort plants. Auxiliary works are the associated machine shops, yards, general construction, and other shops. Iron and steel plants are excluded.

Employment.—Employment at these extractive plants declined approximately 8,500 men from 1943 to a total of 47,600 men in 1944. Man-hours of work performed in 1944 were well below 1943 and totaled 124,300,000 hours. The declines in men and man-hours were sharp in the direct process of extraction and also in the auxiliary

EMPLOYMENT AND ACCIDENTS IN THE MINERAL INDUSTRIES 1559

works. The plants processing miscellaneous metals had the largest employment of the several plant groups in 1943 and 1944 owing to the great expansion in plants producing aluminum and magnesium metals.

Employment and accident data at primary smelters, refineries, reduction plants, and auxiliary works in the United States, 1942-44, by metals

¹ Includes smelters, refineries, reduction, roasting, electrolytic, retort and all other plants producing non-ferrous metals.

² Includes maintenance and repair shops, yards, general construction, and other associated works.

³ 1942: Includes mercury, antimony, and tin plants; 1943-44: Includes mercury, antimony, tin, magnesium, and aluminum plants.

Accidents.—The combined frequency rate of 26.85 per million man-hours for fatal and nonfatal injuries was relatively unchanged in 1944 from 1943. Injuries to workers in the extractive processes occurred slightly more frequently in 1944, whereas injuries to employees in the associated works were slightly less frequent than in 1943. Workers in copper plants had the best over-all safety record of the several classes of plants in this group in 1944.

GENERAL SUMMARY

By J. S. McGRATH

Nothing in history has demonstrated as emphatically as World War II the vital value of predominant access to the world's resources of strategic mineral raw materials, and maintenance of control in the hands of the United Nations has been inevitable to the final outcome. During the course of the struggle all former production records have been surpassed. Most items are believed to have reached their peak years in 1942 and 1943, with relaxation in military requirements reflected in the outset of a decline in 1944. Outstanding exceptions are petroleum, the fuel of war, which established an all-time production record in 1944, and the precious metals, which are not essentially strategic and have been declining steadily since 1940. Transportation facilities and shortages have affected fluctuations in output and emphasized again the fact that no nation is completely self-sufficient in resources required either to wage war successfully or to conduct a balanced peacetime economy.

The Allied victory in Europe, in sight at the close of 1944, had been preceded by a year during which extensive wartime discussions of world security were held. These eventually crystallized into a United Nations Charter approved in June 1945 by representatives of 50 countries. Between August 21 and October 7, 1944, representatives of Great Britain, United States, U. S. S. R., and China met at Dumbarton Oaks, Washington, D. C., to discuss the establishment of a world organization to maintain peace and security. Tentative and incomplete proposals were prepared and submitted for study to the Governments concerned, and these proposals ultimately served as a basis of discussion by the complete United Nations Conference that convened in San Francisco on April 25, 1945.

The Atlantic Charter, a joint declaration (now regarded as somewhat nebulous) by the Prime Minister of Great Britain and the President of the United States on August 14, 1941, provided for access of all nations on equal terms to the trade and to the raw materials of the world needed for their economic prosperity. The Charter of the United Nations, approved by the San Francisco Conference on June 25, 1945, has as its over-all purpose the maintenance of international peace and security, and to that end one of its four provisions is "to achieve international cooperation in solving international problems of an economic, social, cultural, or humanitarian character * * *"

It was evident toward the end of 1944 that, in those countries of the world where the internal economy is supported chiefly by the mining industries and where export markets for mineral commodities for generations have represented the principal sources of revenue, potential burdensome surpluses and widespread distress were problems of almost immediate concern to the Governments involved. It likewise was apparent early in 1945 that "international cooperation in solving international problems of an economic, * * * character * * *" would be the only means of coping with the serious aftermath of the wartime mineral development and procurement program. These problems pertain especially to the Western Hemisphere, where the United States during the war period consumed on an unprecedented scale practically all minerals available throughout Latin America, in most countries of which annual rates of production surpassed all prior levels.

Insofar as data are available, this chapter briefly records the highlights of the mineral production and trade of foreign countries in 1944 and earlier war years.

BRITISH DOMINIONS OF NORTH AMERICA

By FRANK L. FISHER

CANADA

Canadian mineral production was valued at \$485,924,000¹ in 1944 compared with \$530,054,000 in 1943. Metal production decreased

¹ All references to dollars are in terms of Canadian dollars. The official buying rate for drafts on New York is 1 Canadian dollar equals 0.90909 United States dollar.

14 percent in value. The total value of fuels, which includes coal, natural gas, crude petroleum, and peat, increased 7 percent mainly by an allowable increase in the producer's price of coal. Production of industrial minerals and structural materials showed little over-all change from the value for the previous year. Ontario contributed 43 percent of the value of mineral production, and Quebec and British Columbia were next in order of importance. Nova Scotia had the only marked increase in value of mineral production over 1943. The general decrease was due primarily to an acute labor shortage that prevailed in 1944, to restrictions on gold production, and to a smaller extent to easing of the demand for some strategic minerals.

Gold production decreased 21 percent in value. Platinum and allied metals also decreased sharply from the previous year. The other minerals that showed marked declines in production from 1943 were copper, zinc, lead, silver, iron ore, cadmium, chromite, mercury, selenium, salt, tin, arsenic, bismuth, and cobalt. There was little over-all change from 1943 in the production of nickel, asbestos, coal, petroleum, gypsum, magnesite, peat moss, quartz, sodium sulfate, sulfur, clay products, cement, lime, stone, sand, and gravel. The production of pig iron, steel ingots and castings, magnesium, molybdenite concentrate, barite, mica, antimony, and tellurium increased for 1944.

Shipments of iron ore from Steep Rock Iron Mines, Ltd., were begun during the year. The discovery of several extensive iron-ore deposits was reported—in Labrador on the upper basins of the Hamilton and Naskaupi Rivers and in Quebec on the headwaters of the George, Whale, and Swampy Bay Rivers.

Gold.—Gold continued to be the most important mine product of Canada in value. Production dropped 21 percent below the preceding year to the lowest since 1931. The 1944 output was 2,885,474 fine ounces. Ontario mines contributed 1,704,457 ounces or 59 percent of the total. Quebec produced 740,744 ounces to continue as the second-largest producer, and British Columbia produced 191,423 ounces for the year. The number of operating mines decreased from the previous year, but considerable prospecting, particularly in the Yellowknife district, was evidenced and indicated quick resumption of gold-mining activity in the immediate postwar period.

Copper.—Output in 1944 amounted to 547,943,586 pounds. The principal sources of the copper were Noranda, Normetal, and Waite Amulet mines in Quebec; the nickel-copper mines of Ontario; the Flin Flon on the Manitoba-Saskatchewan boundary; the Sherritt-Gordon in Manitoba; and the Britannia and Granby mines in British Columbia. The refined-copper production by the two Canadian refineries was 505,741,000 pounds for the year.

Lead.—Lead production was 301,073,919 pounds in 1944. The Sullivan mine of the Consolidated Mining & Smelting Co., Ltd., was the largest producer. Lead concentrates were also produced in Quebec, Ontario, and Yukon Territory.

Nickel.—Nickel production for the year totaled 275,213,106 pounds, and all came from the Sudbury area; the International Nickel Co. furnished 93 percent, Falconbridge Mines 6.2 percent, and others 0.8 percent. A marked decrease in the production of platinum and its associated metals was noted.

Silver.—The output of silver continued to decline, with 13,586,502 fine ounces produced during the year, entirely from the treatment of ores of other minerals. The Sullivan mine at Kimberley, British Columbia, was the largest producer.

Zinc.—Zinc production amounted to 561,072,538 pounds for the year. The Sullivan mine at Kimberley, British Columbia, was the principal source. The Flin Flon mine of the Hudson Bay Mining & Smelting Co. was another important producer.

Other metals.—The production of several strategic metals was stimulated by war demands during the year. A well-established magnesium industry was developed. Tin was produced from the tailings of the Sullivan mill at Kimberley, British Columbia. Chromite, tungsten, molybdenite, and mercury were produced during the year, but the easing of demands for these metals retarded development before the end of the year, and in some instances production actually ceased.

The production of the following metals was also reported for the year: Antimony, arsenic, bismuth, cobalt, iron ore, manganese, selenium, tellurium, and titanium. Information on the production of pitchblende products was not available.

Asbestos.—Canada continued to be the world's greatest producer of asbestos. The mines, situated in the Eastern Townships of Quebec, produced 419,265 short tons during the year. The bulk of it was exported unmanufactured to the United States.

Feldspar.—The production of feldspar totaled 20,494 tons and came from the Provinces of Ontario and Quebec.

Other nonmetallic minerals.—Production of corundum, graphite, and mica were reported during the year and resulted from the war demands for strategic materials. The corundum production was from reworked tailings. Graphite production amounted to 1,565 tons, all of it coming from the Black Donald mine in Renfrew County, Ontario. Mica production was 6,087,627 pounds. Much of the mica comes from the Eau Claire area near Mattawa, Ontario, where the crystals are phenomenally large, some measuring 5 by 8 feet across. The production of the following industrial minerals was also reported for the year: Barite, clay, cement, fluorspar, gypsum, iron oxides, lime, magnesitic dolomite, brucite, nepheline syenite, peat moss, phosphate, pyrites (sulfur), quartz, salt, sodium carbonate, sodium sulfate, talc, and soapstone.

Coal.—Coal production totaled 17,010,117 short tons for 1944, a decrease from the previous year. Alberta was the leading producer, followed by Nova Scotia, British Columbia, Saskatchewan, and New Brunswick.

Natural gas.—Production of natural gas was 45,956,800 M cubic feet for the year. Alberta is the leading producer, with the Turner Valley field contributing the bulk of the production. Ontario, New Brunswick, and Saskatchewan also reported production.

Petroleum.—Total petroleum production for the Dominion in 1944 was 10,071,100 barrels. The Province of Alberta continued to provide the bulk of the Canadian output, and additional production was reported from Northwest Territories, Ontario, and New Brunswick. There was a record amount of exploration and drilling in Alberta and Saskatchewan during the year in search of new fields. No discoveries were made in Saskatchewan, but in Alberta several new producing

areas were reported. The Canol pipe line operated throughout the year and, at the end of 1944, 58 wells in the Norman Wells field were capable of producing oil.

NEWFOUNDLAND

The mining industries of Newfoundland operated on a stable basis in 1944. The Wabana iron mines produced 517,530 short tons of iron ore, a slight decrease from 1943, and the Indian Head mines reported production of magnetite. The Buchans mine operated at capacity throughout the year with a production of 405,500 short tons of crude copper-lead-zinc ore. Two companies produced 65,254 short tons of fluorspar. No talc was produced during the year, but shipments were made from stock. Prospecting and geological studies continued; specific interest was shown in coal, molybdenum, gold, asbestos, and copper. The exports of mineral products for the fiscal year 1944 totaled \$9,029,416—an increase of \$1,847,601 over the previous fiscal year.

MIDDLE AMERICA ²

By SUMNER M. ANDERSON ³

BRITISH WEST INDIES

Barbados.—In addition to minor quantities of limestone, sandstone, and salt, Barbados produces and refines crude petroleum from shallow wells for domestic use. Production, never important, has declined during the war years to less than a thousand barrels in 1944 and is insufficient to meet local requirements. Less than a hundred tons of natural asphalt is also produced annually for export.

Jamaica.—Limestone quarrying and irregular recovery of salt from sea water constitute the only mineral industries of Jamaica. In 1942 and 1943 large, low-grade bauxite deposits estimated at 100,000,000 tons, were discovered in both the northern and southern parts of the island. Early in 1944, after examination by three companies, the Jamaica Bauxite, Ltd., was formed as a fully owned subsidiary of the Aluminum Co. of Canada, Ltd., but development of the deposits has not yet been initiated.

Trinidad.—The famous asphalt lake continues to maintain Trinidad in top position among the natural asphalt producers of the world, even though production has declined steadily since the peak year 1927. Production figures have not been revealed since 1941 when output was 81,753 metric tons.

Petroleum production probably reached about 25 million barrels in 1944, but official figures are not available. About eight large and half a dozen or more small companies send crude petroleum to four principal refineries and in export to England, the United States, and Canada. All refinery production, exclusive of moderate amounts required for domestic use, are exported, normally to widely scattered

² Anderson, S. M., Minerals Review of Latin America, 1939-44. Bureau of Mines Foreign Minerals Survey, vol. 2, No. 4, 1945 (see for more detailed review).

³ Export sections by A. Taeves

destinations. Quantities and distribution of exports in recent years have not been officially revealed.

Trinidad also has a small quarrying industry of local importance only.

Other islands.—Mineral industry elsewhere in the British West Indies is confined to unimportant production of salt, lime, and phosphate rock.

CUBA¹

Chromite.—The mining of refractory-grade chromite in Cuba in 1944 was restricted to 50 percent of 1943 production because of the large stock piles accumulated in the Island, from which withdrawals for shipment advanced exports to the United States to a position 6 percent higher than in the preceding year and 72 percent greater than production. Reduction of output actually dates from October 1943, when purchases were suspended by the Metals Reserve Company and resumed by private industry. The Cayoguan mine near Punta Gorda supplied considerably more than half of the 173,220 metric tons of ore mined in 1944, and the remainder came from mines of the Juragua Iron Co. and E. J. Lavina & Co. in the Camaguey district. Reserves in the Punta Gorda and Camaguey areas are such as to insure production adequate to meet export demand in 1945, which may equal or even exceed that of 1944.

Production of lump metallurgical-grade chromite responded to increased demand with increased output of Bethlehem Steel's Caledonia mine in the Mayarí district, augmented slightly by about 2,300 tons from small lenses exploited by Cia. Miranda-Gasset in the Sagua de Tanamo district. Although total chromite production decreased in 1944, that of the metallurgical grade advanced more than 150 percent over the 1943 tonnage to 18,911 metric tons. Development of new deposits in the Mayarí district, however, are not considered to be economically justified at present world prices.

Copper.—Copper-ore production in 1944 advanced slightly over 1943 to 6,584 metric tons of contained metal, but the general trend for several years has been downward, reflecting the depletion of ore reserves at Cuba's only important copper mine at Matahambre in the Province of Pinar del Rio. Early in 1944 new, important reserves were developed, and downward trend of production is expected to show an upward turn in 1945. Of the total 1944 output, about 80 tons of copper-in-ore was supplied by 14 small mines in the Provinces of Oriente and Pinar del Rio, under the stimulus of a purchasing agreement with the United States Commercial Company that functioned from March 1943 through September 1944.

Precious metals.—Mining of gold and silver ores has not been reported since 1941. Production today is entirely incidental to the mining of other ores, mainly copper, with which the precious metals are associated in negligible quantities.

Iron.—The Mayarí mines suspended operations in 1943 and 1944, and ore production dropped to the level of output of magnetite and hematite, all of which is being stock-piled, by the only remaining mine of the same company at Firmeza. Production amounted to only 28,370 metric tons in 1944, and the outlook for 1945 is not encouraging.

¹ Review prepared from data supplied by C. A. Botsford, U. S. minerals attaché, Habana.

Manganese.—At the close of 1944 the manganese procurement program of the United States Commercial Company was restricted to the purchase of ores containing 47 percent or more manganese. This curtailment was partly offset by purchases of private buyers who entered the field and contracted for the output of two of the most important mines producing ores averaging 45 percent manganese. However, production dropped from 311,214 metric tons in 1943 to 257,864 tons in 1944. Cuban manganese deposits occupy a broad zone in the Sierra Maestra in Oriente Province, and ore is mined by about 70 small operators.

Nickel.—Production of nickel oxide at the plant of the Nicaro Nickel Co. at Nicaro, Oriente Province, started in December 1943 and increased continuously throughout 1944 to a total output of 6,260 metric tons in that year, derived from 587,573 tons of ore. Full-scale operation is expected to be attained by the middle of 1945, when the production rate should become stabilized. Mechanical and metallurgical problems have been successfully solved for the recovery of nickel oxide from ore by an ammonia-lixiviation process. It was originally planned that the oxide would be reduced to metallic nickel by electric smelting in Wilmington, Del., but recent tests at the steel furnaces have shown that intermediate smelting is unnecessary, and the oxide is now introduced direct into the steel furnaces.

Barite.—Beginning in 1936, exports of Cuban barite rose to a peak of 16,223 tons in 1941 and dropped to 3,158 tons in 1943. Quarrying for the Mineral Products Corporation's grinding plant at Regla, Habana, was suspended in 1942. In 1944, because of short supply in the United States, the United States Commercial Company contracted for 10,000 short tons (907 metric tons) of ground barite of specifications customarily used in oil-well drilling, and slightly more than half this amount was shipped during the year from stocks on hand.

Magnesite.—The mining and export of Cuban magnesite extended from 1939 into 1944, when it was suspended because of the development of large scale production in the United States. The peak year was 1941, when production from small pits near Santa Clara amounted to 16,223 tons.

Miscellaneous minerals.—Marble and other building stone, crushed stone, sand, gravel, clay, cement, gypsum, salt, and pigment earths are produced at various localities for local use and to some extent for export. Also in 1944, for the first time, 5 tons of anthophyllite asbestos were mined and exported to the United States for use as filtering fiber.

Natural asphalt.—Asphalt distributed through every Province in Cuba is of three types: Gilsonite, asphaltites averaging about 20 percent ash, and asphaltites averaging about 40 percent ash and 5 to 7 percent sulfur. Gilsonite is chiefly exported, and asphaltite up to 20 percent ash has been in local demand for fuel since restrictions on fuel imports were brought about by war conditions. The greatest concentration of asphaltic resources is in the Provinces of Pinar del Rio and Santa Clara. Production in 1943 and 1944 amounted to 45,000 and 4,000 metric tons, respectively.

Petroleum.—Cuban petroleum migrated from its source beds to accumulate in shattered pockets in serpentine that have been tapped in three developed fields, none of which is of major importance. No commercial production has been found in sedimentary rocks, the usual depository in the world's great oil fields.

The Bucuranao field in the Province of Habana produced heavy-gravity crude petroleum from 1914 to 1943, in which year the field was said to be exhausted. Output had steadily declined to 1,200 barrels in its last year of operation.

The Motembo field in the western part of Las Villas Province produces a clear, colorless naphtha or natural gasoline that is used in automobile engines in its natural state. Discovered in 1881, the field was not developed commercially until 1934. Production has declined steadily from its peak of 160,457 barrels in 1941 to 94,171 barrels in 1944. More than half the holes drilled are dry, and the ratio of dry holes to producing wells is increasing.

The Jarahuca field near the eastern border of the Province of Las Villas was discovered October 16, 1943. The product, a natural-gas oil, is used to some extent for motor fuel without refining. However, about half of that produced is too heavy for such use, and a part is processed at a newly installed skimming plant at the field and a part refined at the small plant of the Union Oil Co. that formerly treated the crude of the Bucuranao field. The entire output of the field, amounting to 14,831 barrels in 1944, finds a ready local market, and the trend of field development is upward.

At present the Standard Oil Co. of Cuba (Standard Oil Co. of New Jersey subsidiary) and the Estrella Co. (Shell and others) are engaged in petroleum exploration in Cuba, using survey parties and test drilling.

Exports.—Cuba's exports of metallic ores and concentrates in 1944, all of which went to the United States, amounted to only 4.2 percent by value of total Cuban exports of all commodities. Exports of nonmetallic minerals and hydrocarbons have not been completely reported but are known to be of small consequence in comparison with metallic ores and concentrates, which were valued at about \$US18,108,000.

Foreign trade in diamonds has not been mentioned in the preceding discussion because diamonds are not produced in Cuba, but it is of interest in indicating progress in the cutting industry established during the war by European refugees. In 1944 Cuba imported 201,983 carats of rough diamonds from the United States valued at \$2,543,000, and in the same year exported to the United States 43,179 carats of cut and polished stones valued at \$6,575,000.

DOMINICAN REPUBLIC

Gold.—Production of placer gold, normally small, has dropped to less than 1,000 ounces in 1943 and 1944.

Bauxite.—Deposits of bauxite estimated at 20,000,000 tons of probable ore have been examined by the Reynolds Metals Co. and the Aluminum Co. of America. Development plans have not been announced, but future commercial importance is a possibility.

Miscellaneous minerals.—Lime, gypsum, and salt are produced in minor amounts. Exploration for petroleum resulted in the production of 6,000 barrels in 1941 but no commercial quantities since.

HAITI

Haiti produces insignificant amounts of placer gold (161 troy ounces in 1944) and about 8,000 metric tons of sea salt annually. Lime and limestone, building and construction stone, and clay are produced in unreported quantities. Potentially important are bauxite deposits discovered in seven localities during and since 1943, of which the Ste. Croix area of the southern peninsula holds the most promise. Surveys of deposits are being conducted by the Reynolds Mining Corp., which was granted a concession in February 1944.

The Atlantic Refining Co. is continuing prospecting and drilling started in 1943 in structures that appear to be favorable to the accumulation of petroleum.

NETHERLANDS WEST INDIES

Aruba and Curaçao.—Though the Netherlands West Indies produce no crude petroleum, the life blood of their economy flows in the great petroleum refining industry that occupies the islands of Aruba and Curaçao. The Aruba refinery of the Lago Oil & Transport Co., a subsidiary of the Standard Oil Co. of New Jersey, is estimated to have produced between 55 and 60 percent of the refined output of the Netherlands West Indies in 1944, with the remaining 40 to 45 percent supplied by the Curaçao refinery of Curaçaosche Petroleum Industrie Maatschappij, owned by the Dutch-Shell Oil Co. Supplies of crude petroleum refined on Aruba and Curaçao represent roughly 60 to 80 percent of Venezuela's total production and 15 to 40 percent of Colombia's total. About 90 percent of the refined products have been distributed to the armed forces of the United Nations in the various theaters of war and the remainder to European neutrals and Latin American commercial outlets through distributing agencies of the United States Government. Production and export figures have not been released since 1938, but exports are estimated at 134,000 barrels in 1943 and 171,000 barrels in 1944.

Aruba and Curaçao produce insignificant quantities of salt and Curaçao mines phosphate on a small scale at Newport.

Other islands.—A small salt industry operates on the islands of Bonaire, St. Eustace, and St. Martin.

MEXICO

By J. R. KEIGHLEY

The importance of the mineral industry to the Mexican economy is indicated by the fact that, in terms of value, mineral products comprise approximately three-fourths of all exports. For more than four centuries Mexico has been one of the world's most important mineral-producing areas. During that time it is estimated that more than one-third of the world production of silver was mined in Mexico. The Republic ranks also among the world's leading producers of lead, zinc, gold, silver, copper, antimony, arsenic, molybdenum, bismuth, cadmium, fluorspar, graphite, strontium ore, and petroleum. Mexico has the second largest iron and steel industry in Latin America. Production of cement, gypsum, clays, and building materials is

pertinent to Mexico's internal economy, but reliable figures are not available.

The decline of mineral output in 1944 below the record rate of 1943 was attributable mainly to three causes. The United States Commercial Company canceled contracts for celestite, mercury, and tungsten, causing a fear among other producers that contracts covering many or all minerals would be canceled. A general strike of mining and smelter workers went into effect on June 8 when practically all mining ceased, and many properties were idle for several months before wage disputes were settled. A shortage of gasoline and the poor service given by the railroads caused concentrates and metals to accumulate at numerous places throughout the country, handicapping mining operations.

Antimony.—Mexico is second only to Bolivia in the production of antimony, with an output of 10,931 metric tons in 1944 compared with 13,682 tons in 1943. About 95 percent of the output is exported to the smelter of the Texas Mining & Smelting Co. at Laredo, Tex.

Arsenic.—Mexico's output of white arsenic dropped from 20,301 metric tons in 1943 to 15,306 tons in 1944. Production is a byproduct in the smelting of principally arsenical lead ores at the plant of the American Smelting & Refining Co. at San Luis Potosí and the American Metal Co. plant at Torreón, Coahuila. Mexico is second to the United States in production of white arsenic.

Bismuth.—Bismuth is exported principally as bismuth-lead bars produced at the reduction plant of the American Smelting & Refining Co. at Monterrey. Production of 165 tons in 1944 represented a decrease of 10 tons from that of 1943. Some bismuth ore is mined at the Rey de Bismuto mine near Culiacán, Sinaloa.

Cadmium.—The cadmium content of flue dust exported to the United States assures Mexico of second place in the world as a producer of cadmium. Considerable amounts are recovered in the United States from the treatment of zinc concentrates exported from Mexico. If this content were included with that contained in flue dust, Mexico might be the largest producer, with an estimated 2,300 tons annually.

Copper.—During World War II the copper industry was stimulated by financial concessions justifiable only during an emergency, but the increases in production effected by these measures were only moderate and will disappear when the present concessions are abolished. Production of 41,300 metric tons in 1944, of which 32,974 tons were refined copper, represented a 17-percent decrease from 1943 output. With one exception in Baja California, the principal companies are American-owned, and all the copper produced is exported to the United States.

Gold.—Production of gold in Mexico has declined steadily from 883,117 troy ounces in 1940 to 508,882 ounces in 1944. It is recovered principally from ores of other metals, and the most important producer is the Real del Monte silver mine of the Cía. de Real del Monte y Pachuca, subsidiary of U. S. Smelting, Refining & Mining Co.

Iron and steel.—Although Mexico has many iron-ore deposits, the only major source present is the Cerro Mercado deposit near Durango. The property is owned by a subsidiary of Cía. Fundidora de Fierro y Acero de Monterrey, S. A., the principal producer of iron and steel. Annual production of ore is approximately 180,000 tons containing

62 percent iron. Most of the ore is shipped to Monterrey to the Compañía Fundidora's blast-furnace plant, which has a daily capacity of 900 tons of pig iron. Production of pig iron, which has been limited by a serious shortage of coke, dropped from 147,000 tons in 1943 to 135,000 tons in 1944. The domestic demand for all forms of steel has kept the company steel plant and rolling mills working at capacity. Altos Hornos de Mexico, S. A., at Monclova, Coahuila, began producing pig iron in its new plant in 1944, output included in the figure cited above. The company has one blast furnace with a capacity of 300 tons per day.

Lead and zinc.—Mexico is the world's fourth-largest producer of lead and zinc, most of which was exported to Europe and the Far East before 1940 but to the United States since that time. More than a hundred small mines, principally in the States of Chihuahua and Nuevo Leon, sell their ores or concentrates to large American companies for refining or direct shipment in crude form. In 1944 production amounted to 7,011 metric tons of lead-in-concentrates and 178,270 tons of refined lead, and 169,717 tons of zinc-in-concentrates and 49,248 tons of refined zinc. Compared with 1943, this represented an over-all decrease of 15 percent for lead and an increase of 11 percent for zinc. Mexico has furnace-charging capacities of about 1,100,000 metric tons in five lead smelters, 294,000 tons in two lead refineries, and 90,700 tons in one zinc smelter.

Manganese.—Production of manganese ore is solely a war-stimulated enterprise that has been pushed to 29,000 tons in 1944 to supply some of the United States requirements. Only a small percentage of producers could compete on an open market. Principal output is from the Lucifer mine near Santa Rosalia and the El Galivan property near Mulege, both in Baja California.

Mercury.—The significant increase in the production of mercury from 7,376 flasks in 1939 to 32,442 flasks in 1942 was due to the rise in price. The principal mines are Nuevo Mercurio and Sain Alto in the State of Zacatecas and the Huahuaxtla in the State of Guerrero. When the price fell from \$196 per flask to \$96 in 1944, the small, high-cost enterprises closed down, and production was stepped down to 16,063 flasks.

Molybdenum.—The output of molybdenum is almost entirely from Cananea, Sonora, where a byproduct concentrate is segregated at the flotation plant of the Cananea Consolidated Copper Co. In 1943, 1,885 tons of concentrate were sent to the United States for transshipment to the United Kingdom and the U. S. S. R. In 1944 shipments dropped to 1,188 tons containing approximately 720 tons of metal.

Silver.—About one-third of the world's silver is mined in Mexico from silver ores and silver-lead-zinc ores. The most important producers are in Zacatecas, Chihuahua, and Hidalgo. Production in 1944 amounted to 76,717,515 troy ounces.

Strontium.—Strontium salts are used extensively only in time of war, and production is likely to decline when the demand for tracer bullets and flares abates. Principal production is from the Providencia mine at Villa de La Paz, San Luis Potosí. United States imports of Mexican strontium ore dropped from 10,033 metric tons in 1943 to 2,308 tons in 1944.

Tin.—Most of the 300 to 400 tons of alluvial tin produced annually is consumed domestically. The Cía. Metalúrgica de Mexico, S. A., operates a tin smelter at Tlalnepantla, near Mexico City.

Tungsten.—The two most important districts producing tungsten ores are the State of Sonora and the Ensenada area in Baja California. The increased production from 193 metric tons in 1942 to 516 tons in 1943 and 266 tons in 1944 was accompanied by a decline in grade of the concentrates exported.

Nonmetallic minerals.—Production of nonmetallic minerals is continually increasing. Salt, sulfur, gypsum, cement, and building materials are produced in substantial quantities but few reliable statistics are available. The output of fuller's earth, diatomite, kaolin, optical calcite, and semiprecious stones is also increasing.

Fluorspar.—Mining of fluorspar on a relatively extensive scale was brought about by the war. About 70 percent of the total production now comes from the Azul mine, State of Guerrero. Exports have climbed from 9,271 metric tons in 1940 to 56,450 tons in 1944.

Graphite.—United States requirements for "amorphous" graphite are met largely by imports from Mexico. Production is principally from the southern part of the State of Sonora. The United States Graphite Co. and Superior Flake Graphite Co., two companies controlled by American capital, supply a large part of the production, which amounted to 20,677 tons in 1943 but dropped to 12,977 tons in 1944.

Mica.—Unimportant production of only about 100 tons of mica annually is entirely from the Cía. Mercantil de Oaxaca, operating in the State of Oaxaca.

Coal.—The Sabinas coal field in the State of Coahuila is the major source of coal, with reserves estimated at 1 billion tons. The Cía. Carbonifera de Sabinas, subsidiary of American Smelting & Refining Co., operates by far the two largest mines in the country, Rosita No. 6 and Cloete No. 1. The coal is soft and friable, ash content is high, and moisture is 1 to 2 percent. Many other extensive coal deposits exist in Mexico, but few of these have been developed. Production dropped from 1,053,485 tons in 1943, the peak year, to 880,331 metric tons in 1944. No coal is imported into the country, but in recent years there has been a shortage of coke due to a lack of enough coke ovens.

Petroleum.—Production of 38,203,105 barrels in 1944 was 3 million barrels greater than in the previous year. The present output is not indicative of potential production but is controlled with relation to domestic requirements and export markets. The annual report also estimated present reserves at 800,000,000 barrels. The peak year for production was 1921, when approximately 193 million barrels were produced. More than half of the country's production is from the Poza Rica field, which began producing shortly before the 1938 expropriation of foreign holdings. Exploratory work and drilling increased considerably in 1944, but no new discoveries have been made in recent years.

Exports.—Mineral exports decreased with falling production in 1944. Exclusive of nonmetallics and petroleum, exports were valued at \$70,212,587, an 18-percent decrease from the previous year's total of \$86,043,019. Almost all exports were shipped to the United States. Decreases were reported in gold, silver, copper, lead, antimony,

graphite, mercury, arsenic, cadmium, tin, tungsten, molybdenum, celestite, sulfur, and coal. The most important increase was in shipments of fluorspar, which amounted to 151 percent. Shipments of bismuth, iron, manganese, and zinc were larger than in the previous year.

COSTA RICA

Gold and silver, in quantities that have dwindled since 1941 to only 3,606 and 6,167 troy ounces, respectively, in 1944, are mined by four small companies in Costa Rica and shipped in the form of concentrates to San Francisco for refining. The outlook for mining in 1945 is not promising. Salt for domestic use is the only other mineral produced.

GUATEMALA

Production of placer gold dropped from 5,058 ounces in 1939 to 126 ounces in 1944, owing largely to withdrawal of the only dredging operation in the country. Production of chromite, lead, mica, quartz crystal, mineral pigments, and sulfur is too small to be of any importance. Salt, amounting to 12,643 tons in 1944, is produced for domestic use by the evaporation of sea water and the boiling of coastal marine earth.

HONDURAS

Gold and silver.—The American-owned New York and Honduras Rosario Mining Co. at San Juancito is the only company currently producing gold and silver in Honduras. Newly acquired properties are expected to be brought into production after the present world war. Total production is exported to the United States.

A small amount of independent placer mining is done in various parts of the country.

Gold and silver production in 1944 amounted to 19,774 and 3,115,352 troy ounces, respectively, all of which was exported to the United States as usual.

Antimony.—A small production of antimony ore (amounting to 71 tons of contained metal in 1944) is mined from at least six small properties. The total output of concentrates is exported to the United States via San Jose, Guatemala.

Salt.—Salt production is steady but insignificant.

NICARAGUA

Gold and silver.—Nicaraguan exports of gold and silver to the United States, indicative of production, amounted to 219,349 and 248,529 troy ounces, respectively, in 1944, showing only a slight decrease from 1943, and the industry is expected to continue operations at even tenor during 1945. Exports are in the form of concentrates.

Although more than 2,000 gold-silver mines are recorded in Nicaragua, most of the production is supplied by five companies with mines at Jabali. In value, exports of gold and silver represent slightly more than half of the total exports of the country. Nicaragua is the leading gold-producing country of Central America.

Miscellaneous minerals.—Cement, salt, sulfur, saltpeter, limestone, building and construction stone, sand and gravel, clay, and mineral earths are produced in unimportant quantities.

Coal.—Exports of coal amounting to 1,267 metric tons in 1943 were more than double those of 1942 and have greatly exceeded imports since 1941. Coal occurs in the Departments of Leon and Carazo. Production data are not available.

Petroleum.—Geologic conditions that appear favorable to the existence of petroleum have been noted in several sections of the country. Two United States petroleum companies abandoned exploratory drilling early in 1944 but are planning a program of seismographic exploration in 1945.

PANAMA

Panama recovers about 10,000 metric tons of salt a year by the evaporation of sea water. Placer gold has not been produced since 1942, and lode mining of gold-silver-copper ores ceased in 1936.

SALVADOR

Gold and silver.—From 1940 through 1944 exports of bullion to the United States, indicative of total metal production of El Salvador, showed a decline of gold from 50,425 to 23,204 troy ounces and an increase of silver from 168,541 to 305,922 troy ounces, suggesting a decrease in grade of ore in terms of gold:silver ratio, and consequently of value, rather than a decrease in the amount of ore mined and processed. The precious metals contribute 6 percent of the total value of Salvadoran exports. Virtually all of the gold and silver produced came from the mines of five companies: Butters Salvador Mines, Ltd.; Minas Montecristo, Inc., S. A.; Compañía Minera de Oriente, S. A.; Comacaran Gold Mining Co.; and Mineral Los Encuentros.

Nonmetallic minerals.—El Salvador's nonmetallic mineral industry is small and of scarcely more than local interest. Limestone and ornamental stone, clay, volcanic ash (puzzolana), and the usual construction materials are abundant, and a few hundred tons of salt are obtainable annually from the evaporation of sea water. Mineral fuels, however, are entirely lacking.

SOUTH AMERICA ⁵

By SUMNER M. ANDERSON ⁶

ARGENTINA

The year 1944 was marked by official awakening to the danger inherent in Argentine economy that has been brought about by the disappearance of supplies of imported metals, and a campaign has been active for the purpose of stimulating every possible development and use of the country's limited mineral resources. The Government inaugurated a school for mining, assisted in the opening of a well-equipped minerals laboratory by the Argentine Trade Promotion Corporation in Buenos Aires, sponsored a mining congress and held a

⁵ Anderson, S. M., Mineral Reviews of Latin America, 1939-44: Bureau of Mines Foreign Minerals Survey, Vol. 2, No. 4, 1945 (see for more detailed review).

⁶ Export sections by A. Taaves.

mining exposition; but production in general has not increased, and that of certain minerals, such as mica and the ores of tungsten and beryllium, still depends to a large extent on demand from abroad. The Government has also initiated the erection of a blast furnace for the production of pig iron at Palpala, and the development of an iron mine at Zapla, 12 kilometers away, in the Province of Jujuy. The silica content of the ore from this mine is very high and great difficulty is anticipated in obtaining suitable pig iron from it. Argentina's steel industry has always depended heavily on imported pig and ferro-alloys and domestic and imported scrap.

Argentine economy is handicapped most by shortages of coal, petroleum, and copper. If relief comes in 1945 it will be in the form of quantitative improvement of imports rather than of the domestic supply situation.

Although complete official production statistics for 1944 have not been received, the order of value of the leading metals produced in Argentina has been reported as tungsten, lead, gold, zinc, tin, and silver. Comparable figures for the leading nonmetallic minerals are not available for 1944, but in 1942 their order of value was petroleum, cement, stone (all types), lime, salt, solid fuels, sand, mica, clays, and mineral water. In 1942, also, the value of total production of non-metallic minerals (including the hydrocarbons) was nearly six times that of the metallic, although if the hydrocarbons are excluded the value of nonmetallic over metallic minerals produced was but slight. Total over-all mineral production falls considerably short of domestic requirements, and Argentina is consequently a net importer of mineral raw materials and products.

Argentina has only two large mines, both in the Province of Jujuy. Northwest of Tres Cruces the Compañía Mineral Aguilar operates one of the world's largest zinc-lead-silver mines, and northwest of Abra Pampa the Compañía Minera Piriquitas works an alluvial tin deposit that was formerly very rich but is now approaching exhaustion. Since 1942 a part of the concentrates from the Aguilar mine have been refined electrolytically in a zinc plant at Uriburu, a suburb of Buenos Aires.

Exports.—The United States received virtually all of Argentina's exports of strategic minerals, amounting in 1943 to about 1,050 metric tons of beryllium ore, 2,252 tons of tungsten ore of 68 percent WO_3 content (or the equivalent of 2,552 tons of 60 percent WO_3 content), 78,474 tons of zinc concentrates, and 401 tons of mica. Exports of beryllium, tungsten, and zinc concentrates were higher than those of 1942 by 45, 38, and 36 percent, respectively, but those of mica showed practically no change.

BOLIVIA

The year 1944 showed a slight net decrease in the production of exportable minerals. As in former years, tin and tungsten constituted the mainstay of the Bolivian economy and contributed approximately 87 percent (72 and 15 percent, respectively) by value of total Bolivian mineral exports, which amounted to slightly more than \$US73,000,000. Minerals representing 63 percent of this value were purchased by the United States, and the bulk of the remainder was shipped to the United Kingdom in the form of tin concentrates.

One trend of the new revolutionary government which came to power on December 20, 1943, was marked by a series of wage increases and social legislation designed to offset the increased cost of living and to improve the lot of Bolivian workers. These measures are mainly at the expense of the mining industry and, coupled with the heavy tax burden, contribute immoderately to mining costs.

The United States Commercial Company continued its contracts with producers for the purchase of tin, lead, and zinc but terminated contracts for the purchase of antimony, bismuth, copper, and tungsten.

Antimony.—The termination of United States purchases was effective in reducing Bolivia from first place among the antimony-producing countries of the world to a position subordinate to that of Mexico. A decline of 58.6 percent was registered from 17,973 metric tons of contained metal in 1943 to 7,448 tons in 1944.

Bismuth.—With an average annual export record of about 13,000 kilograms of bismuth contained in concentrates over the 5-year period 1939–43, Bolivia dropped to a negligible 605 kilograms in 1944.

Copper.—Production and export of copper in 1944, amounting to 6,011 metric tons of contained metal, slightly exceeded that of 1943. Total yearly output, however, is relatively unimportant.

Gold and silver.—The gold and silver produced during 1944, all of which was exported to the United States, was entirely contained as byproduct in the ores and concentrates of other metals. Output of gold amounted to only 4,561 troy ounces, but 6,797,631 ounces of silver places Bolivia in about sixth place among the producing countries of the world and second only to Peru in South America. Straight gold-mining potentialities received a set-back in December when two contracts for the exploitation of gold in the Tipuani Rio Kaka region were abrogated by action of the National Convention and the Executive Branch of the Government.

Lead.—Bolivian production of lead dropped 21 percent from that of 1943 to 9,047 tons in 1944. Compañía Huanchaca de Bolivia is Bolivia's leading producer of zinc and silver and furnishes about one-third or more of the total output of lead.

Tin.—Tin production declined about 4 percent from that of 1943 to 39,341 metric tons in 1944. Virtually all of the tin produced during the year was from mines that have been established for 35 years or longer. The new Tainton-process plant of the Compañía Minero Unificada del Cerro de Potosi and the sink-and-float plant of Patino Mines and Enterprises Consolidated are finished but neither has as yet achieved successful operation. If technical difficulties are overcome the processes should prolong the life of the mines by increased recovery, and the Tainton process should add materially to the actual output of Potosi and possibly other complex and low-grade ores. The 1945 outlook for tin is favorable, with the expectation that production will equal or surpass that of 1944.

The tin-mining industry continued carrying a heavy tax burden, which in total amounted to approximately 25 percent of the prevailing price, or \$US 0.15 per pound of contained tin shipped.

Tungsten.—Tungsten-ore production reached its wartime peak with a 15-percent increase over that of 1943 to 7,935 metric tons (80 percent WO_3) in 1944. During the latter half of the year, however, production declined materially as the direct result of reductions in price offered by the United States Commercial Company, effective

July 1 and November 1. Rich producers will continue operations in 1945, selling by contract with private buyers. The smaller producers (two of whom failed through bankruptcy in 1944) may be expected to suspend operations in 1945.

Zinc.—In 1944 Bolivian zinc production dropped 22.6 percent from that of the preceding year to 16,319 metric tons of contained metal. Under relatively stable prices production in 1945 is expected to improve.

Nonmetallic minerals.—Mica production remains negligible. Sulfur exports fell a thousand tons from the 7,192-ton high of 1943. Shipments were made to neighboring countries. No information has been received relative to operations in the purely domestic cement, stone, clay, and salt industries during 1944. Apparently no effective attempt has been made to exploit diamond-bearing sediments reported in Caupolican Territory in the northeastern Bolivian Andes.⁷

Petroleum.—The 6-percent decline in production of crude petroleum in 1944, as compared with 1943, was attributable to the lack of oil-well supply materials and equipment resulting from wartime restrictions on supply distribution. A decrease in refinery output was attributable to deterioration of distribution facilities.

Of the 314,467 barrels of crude produced in 1944, 86,311 barrels were exported to unreported destinations; about 192,350 barrels went to domestic refineries and the balance to use in crude form, stock, and losses. Bolivia's imports of petroleum products normally exceed crude production.

Exports.—With minor exceptions, the mineral products of Bolivia are sold in export. In 1944 the United States purchased all the copper, gold, and zinc produced, virtually all the antimony, tungsten, and silver, 51 percent of the tin (the remainder destined for England), and 42 percent of the lead. About half of the lead, all the mercury, a large part of the sulfur, and most of the crude petroleum normally exported goes to Argentina.

BRAZIL *

During the war years Brazil has made an effective contribution of strategic minerals to the war industries of the United States and Great Britain. In 1944 Brazil was the source of virtually all the United States imports of quartz crystal, 53 percent of the tantalite, 47 percent of the beryllium ore, 45 percent of the rutile, 41 percent of the tungsten ore, 13 percent of the manganese ore, 10 percent of the zirconium ore, and relatively minor quantities of metallurgical-grade chromite, ilmenite, zirconium ore, industrial diamonds, mica, and talc. Production was generally considered to be at the maximum level for available equipment and facilities; and, with the exception of coal, iron ore, gold, construction materials, fertilizers, and gem stones, mineral activities were directed primarily toward procurement of strategic materials related to the war effort of the United Nations. All purchase agreements between the United States Commercial Company and Brazilian producers expired in June 1944 and were not renewed, but purchasing has continued by United States

⁷ Oppenheim, Victor, *Diamonds in the Northeastern Bolivian Andes*: Econ. Geol. vol. 38, No. 8, December 1943, pp. 658-661.

* Review prepared from data submitted by E. I. Brown, U. S. mineral attaché, Rio de Janeiro.

and United Kingdom Government agencies and by private commercial enterprises, and the United States Commercial Company has granted loans, rented equipment, and given technical aid to expedite and increase the production of such strategic materials as quartz crystal, mica, beryl, and tantalite. The attainment of higher export tonnages was prevented by transportation facilities that are inadequate, slow, unreliable, and expensive and—particularly for tantalite, beryl, and quartz crystal—by obstructive legislation relating to prices, procurement, and limitation of exports.

With the end of the war in Europe and considerable relaxation of demand, the year 1945 presents the problem of finding markets for those raw material products for which production capacities have been expanded but which are no longer required in such exceptional quantities by the war industries. The type of direction and action applied to this problem will determine the extent to which certain of these industries will be able to continue producing. In general, the abundance of easily accessible surface deposits, the presence of reserves of resources in which the United States is deficient, and very low labor costs all favor a satisfactory solution to the problem of postwar mining development. Obstructing a favorable outlook, on the other hand, are the facts that (1) most deposits are small and not adaptable to large-scale mechanization; (2) transportation facilities are inadequate; (3) Brazil is badly deficient in fuel and power; (4) Brazilian capital and enterprise in general is not interested in mining; and (5) mining legislation and taxation are unattractive to foreign capital.

Bauxite.—Bauxite deposits in the Poços de Caldas district are exploited by Campanhia Brasileira de Alumínio, which in August 1944 began producing alumina, C. P. aluminum sulfate, and sulfuric acid at a new plant at Rodovalho, about 80 kilometers from São Paulo. The plant does not yet have facilities for reducing the alumina to aluminum metal. A deposit in Ouro Preto is utilized by a nearby plant of Electro-Química Brasileira, S. A., which initially produced aluminum metal in March 1945, though at a cost said to be abnormally high. A third plant is planned to be located near Campos in the State of Rio de Janeiro to use bauxite from the State of Espírito Santo. Hydroelectric power is not abundant but is believed to be adequate to produce Brazilian aluminum requirements. Production of bauxite in 1944 has been estimated at only 5,000 metric tons.

Beryl, tantalite, and columbite.—These ores are mined together by crude open-pit methods from pegmatite deposits scattered throughout northeastern Brazil. Columbite is also produced from an alluvial deposit near Pouso Alegre in the State of Espírito Santo. Although production tonnages are small (less than 2,000 metric tons annually for the three ores combined), they represent the major portions of United States requirements for beryl and tantalite and a small contribution to the needs for columbite.

Chromite.—Production of chromite, which was limited to a few hundred tons of hand-sorted lump ore yearly between the first and second world wars, reached a peak of 7,813 tons (as indicated by exports) in 1943. The ores range from about 30 to 50 percent Cr_2O_3 . Mining is from open pits without benefit of any major mechanical equipment.

Gold.—Underground gold mines employ about 13,000 workers in the States of Minas Gerais, Paraná, and Rio Grande do Sul and

supply the major portion of Brazil's output of gold. Silver and arsenic are also recovered from the arsenopyrite ores. Placers in at least 10 States comprise the other important source of gold, and it is estimated that in normal times about 50,000 independent miners work these alluvial deposits. The law requires that all gold produced be sold to the Banco do Brazil, but hoarding and smuggling have been practiced on a fairly large scale in 1943 and 1944, and bank purchases of placer gold are believed to be short of production by about 32,000 troy ounces in each of those years. Production has declined steadily from 264,322 troy ounces in 1940 to an estimated 178,300 ounces in 1944.

Iron and steel.—Iron ore is Brazil's most valuable mineral resource and one of the world's outstanding reserves for future supply, estimated at several billion tons and including a billion or more tons of hard hematite ore that exceeds 60 percent iron and is very low in phosphorus and silica. The important hematite deposits are in the State of Minas Gerais. Unworked but potentially important deposits elsewhere include magnetite ores in São Paulo, Santa Catarina, Paraná, Goiaz, and Matto Grosso and a newly discovered large hematite deposit in the new territory of Amapa. Poor transportation facilities have greatly hampered large-scale development of the Minas Gerais deposits, but ore at Caue Peak near Itabira is now being developed and provided with improved railroad transportation and a loading dock at the port of Victoria. An active and expanding charcoal-iron and steel industry is based on 24 small blast furnaces which produced a record 291,211 tons of pig iron in 1944. This pig iron, in turn, was in part converted into 219,304 tons of steel ingots from which 164,656 tons of rolled steel products were made. The new 300,000-ton iron and steel plant of National Steel at Volta Redonda is to be supplied with ore from the open-pit mines near Congonhas do Campo and will produce approximately 225,000 tons of rolled steel products annually when it attains full capacity.

Manganese.—Manganese deposits in Brazil have been rated second to iron in importance. Production amounting to 203,751 metric tons in 1944 has come principally from central Minas Gerais, and Companhia Meridional de Mineração, Ltda., a subsidiary of the U. S. Steel Corp., is the leading producer. The largest-known manganese deposit in the Americas, estimated to contain 30,000,000 tons of high-grade manganese ore capped by an important hematite ore body, is on the Urucum property near Corumba in western Mato Grosso, almost on the Bolivian border. Large capital expenditure will be required before large-scale shipments can be made profitable over the long river route to Montevideo or Buenos Aires.

Ferromanganese is made in two electric furnaces owned by Companhia Electro-Chimica at Saremeha near Ouro Preto, Minas Gerais.

Nickel.—Nearly a dozen deposits of nickel ore consisting of silicates of the garnierite type are known in the States of Minas Gerais, Goiaz, and Bahia, but only one—at Livramento, Minas Gerais—has been worked. There a 2-percent nickel ore is treated by direct reduction in a 20-ton electric furnace to yield a 20-percent ferronickel. The American Smelting & Refining Co. has abandoned as unprofitable its 2-year attempt to develop Brazil's largest known reserve of nickel ore near São José de Tocantins in central Goiaz.

Tin.—Driven by wartime necessity, Brazil started producing tin for the first time in 1940. Principal production was developed in the valley of the Rio das Mortes, Minas Gerais, chiefly by panning alluvial and eluvial deposits. At the 1943 peak, 350 tons of metallic tin were produced. Most of the smelting was done locally, but small amounts were reduced at São Paulo and Rio de Janeiro. Tin produced under these conditions, regardless of cheap labor, sold for \$1.00 to \$1.15 per pound while the world price was \$0.60.

Titanium ore.—Rutile is panned or sluiced from alluvial deposits over a large area of central Goiás and in southern Minas Gerais. Ilmenite is an important constituent of beach sands in the States of Bahia, Espírito Santo, and Rio de Janeiro, where it is associated with monazite. Production of ilmenite has declined in recent years, and at present there is not much interest in it.

Tungsten ore.—Wolframite is mined in the States of São Paulo and Rio Grande do Sul. Output of the underground Inhandjara mine in São Paulo, the largest producer, is supplemented by small open workings near Encruzilhada, Rio Grande do Sul. Scheelite was first discovered in February 1942 in the Borborema Plateau zone in the States of Rio Grande do Norte and Paraíba. Mining reached its peak in August 1943, and the easily mined scheelite was quickly worked out. Production has declined, and shippers must now stand deductions for impurities. Total shipments of tungsten ore attained their peak in 1944 with 2,221 metric tons, 60 percent WO_3 .

Zirconium.—Zirconium ore is recovered from alluvial, eluvial, and vein deposits in São Paulo and southwestern Minas Gerais. A minor amount is also a byproduct of workings of monazite beach sand. Brazilian production dropped from about 17,000 metric tons in the peak year 1942 to 2,152 tons (shipments) in 1944.

Asbestos.—Asbestos production is small and for domestic use only.

Barite.—The barite industry was formerly unimportant but is changing radically with the development of a series of veins at Morro do Serrate, São Paulo. Production amounted to only 300 tons in 1944 but is now proceeding at the rate of about 100 tons per month, and the owners are operating a plant in São Paulo for the production of barium carbonate and barium nitrate. A larger and potentially more important deposit is that of Ilha Camamū, Bahia. Reserves of 1,000,000 tons of barite of 88 to 98 percent $BaSO_4$ have been reported. The deposit is now being developed by Pigmentos Minerais, S. A., which plans to provide a dock and conveyor for bulk loading of ships directly from the plant stock pile and to produce insecticides, paints, and barium compounds for the Brazilian market and a surplus of raw or ground barite for export.

Building materials.—Building materials, such as cement brick, tile, marble, sand, lime, gypsum, and crushed stone, appear to have been in heavy demand recently, but information relative to production and production facilities is incomplete.

Diamonds.—Normally Brazil produces less than 4 percent of the world output of diamonds, and in 1944 it supplied less than 1.5 percent of total diamond imports into the United States. From May 14, 1941, to January 25, 1945, an agreement was in effect between the United States and Brazil whereby Brazil's entire exportable surplus of diamonds went to the United States exclusively. Diamonds are washed from stream gravels in the States of Mato Grosso, Minas

Gerais, Bahia, Goiaz, Amazonas, Para, Paraná, and São Paulo. All of the carbonados, or black diamonds, come from Bahia. In 1944 an estimated 38,000 nomadic workers washed alluvial gravels for 300,877 carats of diamonds, including 38,372 carats of carbonados. A diamond-cutting industry established in Brazil in the past few years will require the importation of rough stones, or many of the refugee cutters will have to return to Europe after the war.

Graphite.—The Companhia Nacional de Grafite Limitada has recently abandoned a deposit worked for several years in São Paulo in favor of one of better grade near Itapeverica, Minas Gerais. A flotation mill with a capacity of 48 tons per month of graphite averaging better than 85 percent carbon has been installed. In 4 months of 1944, 280 metric tons of graphite concentrates were produced. What percentage of output is crucible-grade is not known.

Lithium.—Byproducts of pegmatite mining in 1944 included 600 metric tons of amblygonite carrying 8 percent Li_2O , sold and shipped to England.

Magnesite.—Deposits of magnesite were unknown in Brazil 6 years ago, but the first discovery in Bahia was followed by another apparently larger discovery in Ceará in 1940. Neither of these has been exploited on a large scale, yet it seems reasonably probable that they may prove to be one of the largest known reserves of magnesite, if not the largest, in the world. Magnesita, S. A., owns the deposit near Brumado, Bahia, and expects to ship over a new railroad to its refractory plant in Belo Horizonte. A stack kiln is being constructed at Brumado to dead-burn the magnesite before shipment. At José de Alencar, Ceará, two furnaces similar to lime kilns have been built for calcining magnesite which is sold in Rio de Janeiro and São Paulo. In 1942, 8,000 tons are reported to have been shipped out.

Mica.—Brazil produces mica from pegmatite deposits in the States of Goiaz, São Paulo, and Bahia, but the chief producing State is Minas Gerais, where about 500 properties engage some 12,000 workers in the mining, transport, trimming, and sorting of about a thousand tons of ruby muscovite annually, or double the output of 1938. During 1942 hundreds of trimmers, qualifiers, and inspectors were trained to Indian or Universal standards, with resulting improvement in quality of the mica shipped. Technical conditions are favorable for a 1945 production equal to the 941 tons shipped in 1944, but commercial conditions are contrary.

Monazite sands.—Monazite is produced principally from beach sands at Guarapary in Espirito Santo. The monazite is said to have a thorium content of 6.31 percent. Monazite production amounted to only 870 tons in 1944.

Phosphate.—Two types of phosphate deposits are known in Brazil. The largest, estimated at 10,000,000 tons, is a bauxite deposit at Ilha Traíra, Maranhão, that is unsuitable as an aluminum ore because it carries 20 to 30 percent P_2O_5 . An economic process for converting the raw material to soluble superphosphate has not yet been devised, but the Departamento Nacional da Produção Mineral is experimenting with a process that it believes will be successful. The other known sources of phosphates, and only ones that have been worked, are apatite deposits. Two of these in São Paulo annually supply about 5,000 tons of ore to a Government plant near Ipanema that concentrates

the apatite and produces phosphate fertilizer, though with only partial success.

Pyrite.—About 3,000 tons of pyrite are produced annually by three mines in the vicinity of Ouro Preta, Minas Gerais, and from vein deposits near Rio Claro in the State of Rio de Janeiro. The pyrite contributes to the production of sulfuric acid in five known plants.

Quartz crystal.—Brazil is the world's best and largest source of quartz crystal of piezoelectric quality. It occurs in relative abundance in the States of Minas Gerais, Goiaz, and Bahia, and most of the production is from widely scattered unorganized sources and shallow surface deposits worked by hand. Final grading and classification are done in Rio de Janeiro and Bahia, where the United States Commercial Company operates laboratories. Ninety percent of all the quartz produced reaches Rio de Janeiro or Bahia from the interior through a succession of storekeeper dealers, to be exported 1 to 6 months later, after sorting. Export figures are consequently the only index to production, which undoubtedly reached its all-time peak in 1943, when shipments amounted to 2,411 metric tons, and dropped to 1,122 tons in 1944. The United States Commercial Company has announced that it will continue purchasing during 1945. This will give some degree of stability to a market that is certain to decline after the war.

Salt.—In 1944, 453,600 tons of common salt were produced for domestic use by the solar evaporation of sea water in 12 States.

Gem stones (except diamonds).—The volume of production of semi-precious stones has been reduced during the war by diversion of labor to the mining of more strategic minerals, but more cutting is being done by the refugee cutting industry, and prices are higher than normal. More gem material comes from the pegmatites of Minas Gerais than from any other State and includes fine-quality amethyst, aquamarine, green and red tourmaline, garnet, white, blue and yellow topaz, citrine, opal, smoky quartz, chrysoberyl, chrysoprase, andalusite, agate, and undoubtedly others.

Coal.—The principal operating coal fields are in Rio Grande do Sul and Santa Catarina. A small field is under limited production in Paraná, and a new field was discovered recently in São Paulo. Production is considerably below domestic needs, which were supplied in 1943-44 as shown in the following table.

Brazilian coal supplies, 1943-44, in metric tons

Production by States (clean coal):	1943	1944
Rio Grande do Sul.....	925, 759	807, 784
Santa Catarina.....	584, 234	540, 874
Paraná.....	40, 000	76, 000
São Paulo.....	6, 000	8, 500
Total Brazilian production.....	1, 555, 993	1, 433, 158
Imports ¹	651, 575	677, 000
Total supply.....	2, 207, 568	2, 110, 158
Exports.....	57, 269	16, 740
Total supply available for domestic use.....	2, 150, 299	2, 093, 418

¹ 1 ton of imported coal is considered to equal 1.4 tons of Brazilian coal in heating value.

Petroleum.—Two small oil fields in the State of Bahia produced 125,000 barrels of crude petroleum in 1944. Operations started in the Lubato field in 1939 and at Candeis in 1940. Reserves have been estimated at only about 1,000,000 barrels, and prospects of important future production are not encouraging.

Export.—Complete mineral-export statistics showing countries of destination are not available for the past 2 years, but information has been presented showing that exports to the United States in 1943 and 1944 rose from 46 to 47 percent of total exports in tonnage and from 51 to 53 percent in value, indicating very little change in proportional distribution. On the basis of actual quantities shipped to the United States in the 2 years, manganese dropped 47 percent, quartz crystal 44 percent, and diamonds 5 percent. The portion of certain mineral exports destined for the United States in 1944 is indicated in the following table.

Brazilian exports of selected minerals in 1944

Mineral	Total exports (metric tons)	Total to U. S. (metric tons)	Percent of total to U. S.
Beryl ore	1,185	1,185	100
Chromium ore	4,721	4,721	100
Ilmenite	2,500	2,500	100
Tantalite	254	254	100
Tungsten ore (60 percent WO ₃ equiv.)	2,221	2,221	100
Carbonados (carats)	10,795	10,795	100
Manganese ore	146,983	146,763	100
Rutile (titanium)	1,564	1,544	99
Zirconium ore	2,152	2,117	98
Diamonds, cut and rough (carats)	192,185	185,850	97
Quartz crystal	1,122	863	77
Mica	941	682	73
Clay	486	135	28
Iron ore	82,895	2,506	3
Pig iron	4,242		
Ferromanganese	1,228		
Graphite	199		
Bauxite	2,979		
Coal	16,740		

BRITISH GUIANA

Bauxite.—The decrease in bauxite production and exports—59 and 54 percent, respectively, from the peak year 1943—was the inevitable consequence of the improved military position of the United Nations which resulted in some relaxation of the demand for aluminum. All 1944 production, amounting to 928,178 metric tons, was from the Demarara Bauxite Co., Ltd.

Gold and diamonds.—Production of gold and diamonds in 1944 dropped 35 and 17 percent respectively, from the output in 1943, continuing a downward trend that started for gold in 1939 and for diamonds during or before 1930. Activity of the only two organized gold producers, Cuyuni Goldfields, Ltd., and British Guiana Consolidated Mining Co., is believed to be fairly well stabilized, and the deterioration of exports to only 7,571 troy ounces in 1944 is attributable largely to temporary and gradual abandonment of gold operations by individual prospectors in favor of more lucrative wartime employment.

Diamond production, which depends wholly upon an estimated 1,500 independent individuals, has declined for the same reason and because of depletion of the more readily available deposits. In 1944

exports dropped to 13,911 carats. With decreased employment in other lines in 1945, it is anticipated that production of gold will reach about 10,000 troy ounces and diamond production about 15,000 carats.

Distribution of exports.—British Guiana continues to be Canada's chief source of bauxite. In 1944, 95 percent of bauxite exports went to Canada, 4 percent to the United States, and 1 percent to the United Kingdom. The United States received 98 percent of the gold and 30 percent of the diamonds exported in the same year, Brazil 2 percent of the gold, and the United Kingdom 70 percent of the diamonds. All of the known mineral production of British Guiana except granite is eventually sold in export.

CHILE

Copper.—Chilean production of refined copper in 1944, for all practical purposes, was the same as in 1943 but may have established a new all-time high by a small margin over the 489,320 metric tons recorded in that year. The contract for the delivery of copper by the three large companies to the United States Commercial Company was renewed to cover the first quarter of 1945. Chile is the world's second largest producer of copper, and the bulk of its output goes to the United States, which leads the world in both production and consumption. Most of the mine production and all of the refining is done by three American-owned companies at Chuquicamata, Portrerillos, El Tiente, and Caletones, but two small custom smelters of Chilean ownership have been operating at Chagres and Naltagua, and about 650,000 tons of ore a year are broken from nearly 100 small mines throughout the country. Failure of the United States Commercial Company to extend its purchasing agreement with small producers is expected to force closure of most of these small mines and consequently of the custom furnaces, with a resulting cut of about 25,000 tons of copper. With this exception the industry is expected to continue operations on a prosperous scale through at least the first half of 1945. About 98 percent of the copper exported is in the form of refined and blister bars; the balance is contained in ores, concentrates, and other crude forms. Well over 90 percent of all the copper produced is exported.

Gold and silver.—From incomplete preliminary figures for 1944, a slight increase over 1943 gold production of 269,807 ounces is indicated, though not over 1941 output. Improved economic conditions in Chile have been reflected in a declining production of placer gold, as much of the placer exploitation represents depression activity, but this has been offset to some extent by increased production of copper, from which a large proportion of total gold output is recovered as a byproduct. In addition, about 25 percent of the total comes from 10 principal and several small gold-lode mines. Silver production, which amounted to 1,093,543 ounces in 1943, follows the same general trends as gold, with virtually no mining being conducted primarily for silver. About 40 percent of the silver output is contained in blister copper, 5 percent in copper concentrates, 20 percent in gold concentrates and precipitates, 30 percent in gold-copper-silver ores, and only 5 percent in primary silver ores that also carry values in arsenic. Chile is the second largest gold and fourth largest silver producer in South America.

Iron and steel.—The Bethlehem Chile Iron Mines Co. operates the only iron mines in Chile at El Tofo in the Province of Coquimbo. Normal production is roughly 1,600,000 metric tons annually, but no ore has been exported to the United States since 1942; production dropped to about 15,400 metric tons in 1944, all of which was shipped to Chile's only iron and steel plant at Corral, owned by Cia. Electro Siderurgica y Industrial de Valdivia. With pig iron from its own furnaces mixed with scrap this company produces annually about 48,000 metric tons of billets and blooms, reinforcing and merchant bars, steel strip, and iron and steel castings. The output of this plant is partly sold in export to Argentina, but most of it supplements Chilean imports of semifinished iron and steel products that are sold to local manufacturers. During 1944 considerable attention has been given to a project for the erection of a new iron and steel plant to be located on San Vicente Bay near Talcahuano and Concepción and operated by a company to be known as Cia. de Acero del Pacifico. Production will be 180,000 metric tons of pig iron and its derivatives annually from ore to be supplied by El Tofo mines.

Manganese.—Manganese ore, which attained peak production of 114,074 metric tons in 1943, is reported to have experienced a poor year in 1944. Production in recent years has been from the Provinces of Coquimbo, Atacama, Antofagasta, and O'Higgins. Production is expected to decline with the end of World War II but may be revived to meet needs of the proposed iron and steel industry.

Mercury.—Mercury production rose from 100 flasks in 1939 and 1940 to 2,563 flasks in 1943, with no report received on output in 1944. The only known production is from cinnabar disseminated in gold ore from the Punitaqui mine in the Province of Coquimbo.

Molybdenum.—Molybdenum occurs in ores of the three big copper companies but is known to be recovered only at El Tiente mine of the Braden Copper Co. Under wartime demand production was pushed from 30 tons of molybdenum-in-concentrates in 1939 to 680 tons in 1943, with the probability that the 1944 figures approached the 1,000-ton mark.

Mineral salts.—Chile's richest source of nonmetallic mineral wealth is the northern desert of Antofagasta Province, which contains extensive beds of such natural salts as sodium nitrate (Chile saltpeter), potassium nitrate, sodium sulfate, sodium chloride (common salt), borax, calcium sulfate, magnesium sulfate, potassium chloride, and sodium carbonate. The steady decline of nitrate production from 1,437,451 metric tons in 1940 to 998,534 tons in 1944 has been attributed to the shipping shortage and the greatly increased capacity in the United States for the manufacture of synthetic ammonia. The same period has seen a parallel decrease in the production of crude iodine, which is a byproduct of the nitrate purification process, while sodium sulfate has improved its position with a better market. Nitrate operations are controlled and quotas set by the Chilean Nitrate & Iodine Sales Corporation, a Government agency.

Sulfur.—Seven principal and various small companies produce sulfur from the volcanic border region adjacent to Bolivia and Argentina, at a rate of about 32,000 tons a year. In addition to supplying domestic requirements, an appreciable export trade has been built up with neighboring countries, especially Argentina and Brazil.

Phosphate.—Production of phosphate rock (apatite) in the Province of Coquimbo has become well-established during the war years and probably passed the 40,000-ton mark in 1944. Sociedad Fabrica de Cemento el Melon is the principal producer, and Cia. Fosfatos de Chile the only other.

Miscellaneous minerals.—Limestone is regularly quarried for building stone, agricultural use, and the manufacture of cement and lime; gypsum for the manufacture of cement and plaster; and clay for cement and for pottery. Salt is recovered from sea water and from desert deposits. Production of mineral pigments and kieselguhr has been reported irregularly. Production of feldspar, quartz, and talc in small quantities was reported for the first time in 1943.

Coal.—Estimates indicate that coal attained an all-time peak production of 2,035,000 metric tons net weight (2,279,693 metric tons gross weight) in 1944. Operation of the two principal coal mines, Lota and Schwager on the Gulf of Arauco, is supplemented by relatively small-scale exploitation of bituminous reserves in the Province of Arauco.

Exports.—Exclusive of iodine, iron ore, and coal, for which figures of shipments have not been reported, Chile exported 1,674,432 metric tons of crude and refined minerals in 1944, of which 1,224,147 tons (73 percent) went to the United States, as against 1,605,293 tons of equivalent materials in 1943, of which 1,183,528 tons (74 percent) went to the United States, showing a slight change in tonnage shipped but no appreciable change in ratio of major distribution.

Normally the value of mineral exports constitutes approximately 83 percent of total Chilean exports.

COLOMBIA

Precious metals.—Colombia is the leading country in South America in the production of gold but takes sixth place in the output of silver. It is the only South American producer of platinum and in the entire world is surpassed only by Canada, Union of South Africa, and probably the Soviet Union. Production of all three metals has been declining moderately but steadily since the peak year 1941.

In 1944, 553,330 ounces of gold and 197,323 ounces of silver were mined together from many placers and lode deposits scattered over 15 Departments and Territories, of which the Department of Antioquia supplied nearly two-thirds of the total output of both metals. About 60 percent of production is from placers and 40 percent from lode mines. Colombia is estimated to contain about 35 percent of the total gold reserves of South America.

Platinum, in the amount of 34,259 ounces in 1944, is also mined with gold, chiefly from streams on the Pacific slope, and about 65 percent of the output is the product of the South American Gold & Platinum Co., which operates several dredges along the San Juan River up from Buenaventura.

Iron and steel.—A small iron furnace at Capitanes has been producing about 1,500 tons of pig iron annually from local siderite ore for the past 3 years, for sale to domestic foundries.

A new steel plant in Medellín, operated by the Empresa Siderúrgica, S. A., apparently started experimental runs in 1942 but did not achieve production of steel on a commercial scale until 1944, when it

began rolling its first reinforcing bars. The plant has two electric furnaces and a third larger furnace on order that will raise the capacity to 30 tons a day. Aside from steel, the furnaces are reported to have been producing cast iron during 1943 for the foundries of Medellín. Thus far the furnaces have been using scrap metal only; but the stock is approaching exhaustion, and the company is contemplating utilization of an iron-ore deposit at Paz del Río, which has been studied extensively during the past year. Chromite, manganese, limestone, and clay are obtained locally. The plant produces its own refractory brick and operates two rolling mills.

Emeralds.—Emerald mines in the famous Muzo district have not reported production since 1934 but are believed to be operating fairly regularly. The Chivor mines were leased by the Government to Chivor Emerald Mines, Inc., in September 1937 but are not known to have been operated since the close of 1940. The Government is said to have accumulated a large stock of emeralds, and sales and exports have no essential relationship to production in any given time period. Both the mining and marketing of emeralds are under strict Government control.

Miscellaneous minerals.—Limestone, gypsum, and clay are quarried for the production of cement. Salt is recovered from sea water and from eight mines. Activity of the United States Foreign Economic Administration in 1942–44 resulted in the production of very small quantities of lead, quartz crystal, mica, and optical calcite. Exploitation of these minerals, with the probable exception of lead ore, is not expected to survive the war.

Coal.—Coal production has risen steadily, beginning in 1941, to pass the half-million-ton mark in 1944, but the figure fell some 11,000 tons short of the 521,453-ton record achieved in 1940. Mines are fairly numerous near Bogotá and throughout the Cauca River Valley between Medellín and Cali. Most of the coal mined is bituminous, and reserves are known to include subanthracite and anthracite. Colombian coal is considered the best in South America, the ash content of some veins analyzing less than 10 percent. Exports have risen from nil in 1940 to nearly 3,000 tons in 1944, with Brazil the principal customer. The bulk of the coal produced is consumed within the country, including a fair portion that is converted to coke.

Petroleum.—In 1944 Colombia produced 22,647,476 barrels of crude petroleum, of which 18,561,431 barrels were exported and 3,854,742 barrels refined within the country. Comparable figures for 1943 showed 13,261,065 barrels produced, 10,723,862 exported, and 3,427,718 refined.

The Tropical Oil Co. sends approximately 50,000 barrels of crude a day from wells in the De Mares concession through its refinery at El Centro, and the refined products are distributed throughout Colombia. Andian International Corp. is the pipe-line company that pipes crude from the De Mares concession to Cartagena for export.

Colombia Petroleum Co. produces about 14,000 barrels of crude daily from the Petrolea and new Tibú-Socado fields in the Barco concession and operates a small topping plant of 500 barrels daily capacity that supplies gasoline and gas and fuel oil to the Barco concession and to marketing areas surrounding Cúcuta. Crude for export is transported over the pipe line of South American Gulf Oil Co. to Corveñas, southwest of Cartagena.

Cía. de Petróleo Shell de Colombia has been producing crude since 1941 from the Casabe concession on the Magdalena River and had 25 wells by the end of 1944. Exploration of part of the company holdings in nine Departments and Territories also led to minor production from the Difficil concession in 1944. Crude for export from the Casabe concession is to be carried to Cartegena through the pipe line of the Andian International Corp. as soon as a line connection from the Shell field is completed. Shell has no Colombian refinery.

Socony-Vacuum Oil Co. of Colombia has started production from two small wells (200 barrels per day each) on the Cantagallo concession in the Magdalena Valley.

These four producers and four other American oil companies are actively engaged in geological and geophysical prospecting for new fields and extensions of established producing areas. The combined holdings of nine American oil companies cover approximately 10,000,000 hectares, or 38,600 square miles, which amount to about 8.7 percent of Colombia's total area.

Exports.—Complete official Colombian export figures for 1944 have not been reported. United States official figures record no imports of gold or silver from Colombia in 1944 but do show 35,320 troy ounces of platinum, representing 11 percent of total imports of that metal and slightly more than Colombia's total production for the year. Colombia's small total shipments of 1,094 pounds of quartz crystal and 1,423 pounds of mica went to the United States.

Of the 18,561,431 barrels of crude petroleum exported in 1944, the United States imported 7,544,747 barrels, representing approximately 40 percent of Colombia's shipments and 16 percent of total United States imports of crude from all sources. Judging by past performance the bulk of the remainder of Colombian crude exports may be presumed to have been destined to Canada and Aruba.

ECUADOR

Metal mining.—Except for placer operations, the mining of gold, silver, copper, and lead in Ecuador is confined to the South American Development Co. at Portovelo and the Cotopaxi Exploration Co. at Macuchi. The Portovelo mine is Ecuador's largest producer of gold and the Macuchi mine the largest producer of silver and copper. The ores contain some lead and insignificant quantities of zinc. In 1942 the Cotopaxi Exploration Co. completed and started operating a small smelter at Macuchi, which recovers copper in the form of blister. All of the blister and concentrates are exported to the United States. Operation of the Portovelo mine in El Oro Province was paralyzed at the end of the year by flooding, followed in January 1945 by break-down of one of the two hydroelectric plants. The year 1944 was a difficult one for both companies because of the stabilized price of gold and silver against increased wages and cost of materials. Gold recovered from placer operations widely scattered throughout the country is sold in accordance with law to the Central Bank of Ecuador. Metal mining in 1944 produced 84,234 ounces of gold, 376,565 ounces of silver, 3,720 metric tons of copper, and 406 tons of lead.

Nonmetallic minerals.—Limestone and gypsum from Guayas Province and fuel oil from local fields are used for the manufacture of

cement, which reached an all-time high of 35,096 metric tons in 1944.

Production of 35,958 tons of marine salt for local consumption in 1944 was well in advance of tonnage in any of the preceding 5 years.

Crude sulfur of volcanic origin is produced in amounts of less than 100 tons annually.

Production of china clay, geyserite, coal, and iron oxide is small and unimportant. The United States has received some sample shipments of quartz crystal from Ecuador, but production on a commercial scale is not anticipated.

Petroleum.—Ecuador produces petroleum in excess of local requirements, and considerable quantities are customarily exported to other countries. Anglo-Ecuadoran Oilfields, Ltd., a British-owned concern, supplies more than two-thirds of the total production. The remainder is contributed by the few wells of six other companies. At present, production is confined to Santa Elena Peninsula, but intensive exploration is being conducted elsewhere by the International Ecuadoran Petroleum Co. and the Shell Oil Co. Total production amounted to 2,892,190 barrels in 1944.

In addition to crude petroleum, gasoline is liquefied from natural gas, and various products are refined at a moderately large plant of Anglo-Ecuadoran Oilfields, Ltd. at La Libertad and a small refinery of Ecuador Oilfields, Ltd., at Cautivo.

Exports.—The United States customarily receives all of Ecuador's exports of metals and metallic concentrates, with the possible exception of placer gold and silver, for which export figures have not been reported. Small shipments of salt and sulfur have been made to neighboring South American countries. Before World War II Uruguay and France were the principal destinations of Ecuador's surplus crude petroleum, with Brazil, Japan, England, and Argentina receiving smaller amounts. Since the beginning of the war Uruguay, Argentina, and Brazil have received larger portions, and in 1943 they were the only importers of Ecuadoran crude. Distribution of natural gasoline by countries has not been reported.

FRENCH GUIANA

French Guiana has no mineral production other than placer gold, which has steadily declined to 18,440 troy ounces in 1944, about half the prewar output. Bauxite deposits are extensive but undeveloped.

PARAGUAY

Paraguay has no established mining or mineral industry.

Of great interest to the petroleum industry is the exploration work now under way in the Chaco by the Union Oil Co. of California. Its contract with the Paraguayan Government is unique in several respects and may well serve as a pattern for future agreements between American oil companies and foreign governments.

PERU*

Peru ranks among the world's leading producers of silver, vanadium, and bismuth and lists gold, copper, lead, zinc, tungsten, and molybdenum among its important metals, with white arsenic rapidly ap-

* Review prepared from data submitted by W. O. Vanderburg, minerals attaché, Lima.

proaching world importance. Petroleum and its products lead the nonmetallic field, and coal, cement, and lime are produced in appreciable quantities. Crude gypsum, clay, and the usual construction materials are produced regularly but in quantities that are not officially reported.

The absence of spectacular expansion during the war places Peru in a favorable position for facing the problem of conversion to peacetime economy without serious difficulty and with little, if any, important shift of markets. The industrial capacity of Peru for the use of metals is very limited, and most of the mine and smelter products are sold in export.

Antimony.—Antimony is obtained from about 70 small mines scattered throughout seven departments. Most of the ore goes to the Oroya smelter, where the Cerro de Pasco Copper Corp. completed a special recovery plant in August 1942. Production of antimony in all forms rose from 847 metric tons in 1939 to 2,681 tons in 1943 and dropped to 1,050 tons in 1944. Sales in recent years have been to the Metals Reserve Company and its successor, the United States Commercial Company.

Arsenic.—In June 1943 the Oroya plant of Cerro de Pasco Copper Corp. began commercial production of white arsenic that reached 6,900 tons in 1944 but failed to attain 800 tons monthly during 1943–44 as contracted for with the United States Commercial Company. The oxide is derived chiefly as a byproduct from arsenious copper and lead ores.

Bismuth.—Peru leads the world in production of bismuth, which occurs as an auxiliary metal with ores from the Colquijirca, San Gregorio, and Cerro de Pasco mines. Bismuth metal has been extracted and refined from Peruvian ores at the Oroya smelter since 1932. Production reached its peak at 483 tons in 1943 and dropped to 416 tons in 1944.

Cadmium.—Peru's cadmium production, amounting to 3,653 and 2,174 kilograms, respectively, in 1943 and 1944, comes from lead-zinc ores of the Cercapuquio mine and zinc concentrates of the Cerro de Pasco Copper Corp. Recovery of the metal in refined bars was begun at the Oroya plant early in 1942.

Copper.—The Cerro de Pasco Copper Corp. supplies about 60 percent of the total copper production of Peru. The remaining 40 percent is distributed among 15 base-metal mines and as a byproduct of 5 gold-silver mines. The Oroya plant is the sole producer of blister copper, and early in 1942 it initiated production of electrolytic copper on a small scale. Production in all forms has declined from the peak of 43,965 metric tons in 1940 to 32,390 tons in 1944.

Gold.—About two-thirds of the gold produced in Peru comes from gold-silver mines and one-third from complex-ore mines in association with base metals. Considerable interest is being shown in gold mining, and several new mines have been developed during the year, notably in and near the coastal region. The sale of gold is unrestricted in Peru, and appreciable quantities of gold obtained from placers in the southeastern montaña are believed to be unreported in official production statistics, which show a steady decline from 285,189 ounces in 1941 to 175,180 ounces in 1944.

Lead.—At 52,501 metric tons, the 1944 production of lead exceeded that of any previous year in Peru's history and represented an increase

of 10 percent over that of 1943. Cía. des Mines de Huaron, Cía. Minera Atacocha, S. A., and Cerro de Pasco Copper Corp. were the chief producers. The three companies combined mined half the Peruvian output in 1944, the other half coming from 15 complex-ore mines and 5 gold-silver mines. All of the refined lead is produced by the Oroya plant.

Mercury.—Interest in mercury mining revived in 1941, and some production was reported in 1942, though not quantitatively, when a 20-ton Gould rotary furnace was installed at the Chonta mine. Production amounted to 326 flasks in 1943 and 152 flasks in 1944. Progress on the construction of a 250-ton mercury reduction plant at the old and formerly very important Santa Barbara mine is proceeding slowly, and completion in 1945 is doubtful.

Molybdenum.—Peru Molibdeno, S. A., which in recent years has supplied almost the entire output of molybdenum concentrates, closed its concentrator in October 1944 because of approaching exhaustion of developed ore reserves and financial difficulties. Subsequently it renewed operations for about 3 months, until its contract with United States Commercial Company was canceled. The only other producer, the Salazar mine, is too small to be of consequence, and Peru's 1945 production of molybdenum is expected to register an abrupt drop. Production on a metal-content basis declined from 166 tons in 1940 to 62 tons in 1944.

Silver.—About 85 percent of the silver produced in Peru is recovered as a byproduct in the treatment of copper, lead, and zinc ores and 15 percent from gold-silver ores. Half of the 15,832,440 troy ounces produced in 1944 came from 5 leading companies and the balance from 20 complex ore mines and 14 gold-silver mines. In the production of silver, Peru ranks second only to Mexico in Latin America and fourth in the entire world.

Tin.—Less than 100 tons of tin are refined annually at Oroya as a byproduct of ores from Cerro de Pasco. No production has been reported, however, for 1944.

Tungsten.—The modest output of 583 metric tons of 60-percent WO_3 concentrate equivalent in 1944 was mostly from the Málaga mines, with the Cahuide mine the only other producer reported.

Vanadium.—Since 1941, when the United States displaced Peru as the world's foremost producer of vanadium, Peru has continued in second place. All production in 1944 was from the Minaragra mine of the Vanadium Corp. of America, where construction of a leaching plant of 200-ton daily capacity was completed during the latter part of the year. The decline in production from 1,150 tons in 1940 to 518 tons in 1944 is largely attributable to the gradual exhaustion of direct-shipping oxide ores.

Zinc.—Preliminary reports indicate that the most important mineral development of the year was a 79-percent increase over 1943 in the mine production of zinc, which is stated to have exceeded 56,000 metric tons of contained metal. Eighty percent of this amount was mined by the leading 4 of 11 producing companies: Cerro de Pasco Copper Corp.; Cía. Minera Atacocha, S. A.; Volcan Mines Co.; and Cía. des Mines de Huaron. Production of refined bars by the electrolytic zinc pilot plant at Cerro de Pasco has been reported as 1,225 tons in 1943 and 1,441 tons in 1944.

Nonmetallic minerals.—The production of cement by two plants established a new all-time high of 248,537 tons in 1944. Production of calcined gypsum, although relatively unimportant, also reached an all-time high in 1944, with 25,190 metric tons, the output of 5 small plants. Sulfur production is solely from Azufrera Panarany in the Department of Tacna. Salt is produced from salinas, wells, and mines at 32 localities in 16 Departments. Mineral waters are sold from 4 towns. Manganese sulfate is obtained as a byproduct of the lixiviation of copper-silver ores by the Lampa Mining Co.

Coal.—Coal-production figures for 1944 have not been received. During the year the Banco Minero del Peru ventured into the mineral-exploitation field for the first time, starting development of the bituminous coal deposits at Oyon, Department of Junin. Sales are to Lima and other urban centers, but the bank also plans to produce coke for the export trade. Of the total country output of 186,996 metric tons in 1943 that of Goyllarisquiza comprised 93 percent, most of which was consumed by the Oroya smelter and the Cerro de Pasco Railroad. Of the five anthracite mines operating in 1943, the Mis Suenos mine at La Galada, the Jose Balta mine at Los Banos, and the Lord mine at Bambas produced 98 percent of the total output. In the La Galada region plans were under way in 1944 to install washing plants to improve the product for sale in export.

Petroleum.—Production of 14,390,961 barrels of crude petroleum in 1944 represented a decrease of only 2 percent from that of 1943 but was about 3 million barrels, or 18 percent, short of the peak year 1936. International Petroleum Co., Cía. Petrólera Lobitos, Petróleo del Estado (Zorritos), and Cía. Petrólera Ganso Azul are the four companies operating in Peru; about 82 percent of production came from International Petroleum Co. and 17 percent from Cía. Petrólera Lobitos, based on 1943 figures. The producing fields are La Brea and Parinas near Talara, Lobitos and El Alto near Cabo Blanco, Zorritos, and Ganso Azul at Agua Caliente. International Petroleum Co. and Cía. Petrólera Lobitos also produced 1,035,219 barrels of natural gasoline in 1944, in proportions of about 90 and 10 percent, respectively. Most of the crude petroleum produced in the country is processed at the refinery of the International Petroleum Co. at Talara. Between 300 and 400 thousand barrels go to the State refinery at Villar, and between 200 and 300 thousand barrels are exported.

Exports.—The United States continued to be Peru's best customer in 1944, receiving (on the basis of preliminary unofficial figures) all of the copper, zinc concentrates, gold, tungsten, vanadium, molybdenum, cadmium, and mica and most of the silver, lead, antimony, and mercury that was exported. The United States was also the largest single recipient of white arsenic, but more than half of that exported was destined to Brazil, Uruguay, Colombia, Chile, and Venezuela. England took the largest part of the manganese sulfate, and neighboring countries in South America received most of the other nonmetallic minerals exported.

SURINAM

Netherlands Guiana

Bauxite.—Surinam is the United States chief source of imported bauxite. Shipments in 1944 were divided between 517,707 metric

tons by Surinamsche Bauxite and 108,097 tons by N. V. Billiton, and the end of the year found large port stocks awaiting allocation of ships by the War Shipping Administration. The all-time peak in exports was reached in 1943 with 1,655,147 tons, and the 62-percent drop in 1944 is attributable to relaxation of military demands and increased utilization of heavily accumulated stocks in the United States.

In December 1944 the Construction Aggregates Corp. of Chicago completed dredging started in June 1943, providing a ship channel $9\frac{1}{2}$ miles long and through a bar at the mouth of the Surinam River that will permit full loading of ships at the river ports.

Gold.—Gold in Surinam is recovered from placer deposits by the use of long toms and sluices and by hand panning. During the war years various defense projects undertaken by the local government are held responsible for diverting many of the independent miners away from their usual activities, with the consequent decline in gold production from the 15,921-ounce output of 1940. Independent operators supplied only 1,323 of the total 5,723 troy ounces produced in 1944. The remaining 4,400 ounces were the product of the only two organized companies in the colony, the Sara Creek Mining Co. and White Water Mines, Ltd.

URUGUAY

Gold.—The only metal mining in Uruguay is for gold in quantities too small to be reported since the 1,364-ounce output of two mines in the Rivera district in 1941.

Nonmetallic minerals.—More important to Uruguay are the deposits of nonmetallic minerals, particularly in the field of construction materials. Reports of production are spotty and incomplete; but talc and mica are quarried and ground locally, and building stone, crushed stone, and sand in surplus of domestic needs figure largely in the export trade with neighboring countries. Two plants at Montevideo and Nueva Carrara produce about 180,000 metric tons of cement annually, using domestic raw materials and imported fuel.

VENEZUELA

Gold.—Gold is the only metal currently mined in Venezuela. Lode mining has been confined to a region in the State of Bolívar about 100 miles southeast of the port of San Felix on the Orinoco River and 12 miles from the town of Guasipati. New Goldfields of Venezuela is the most important of three companies that have continued operations through 1944. Production has declined steadily from 146,792 troy ounces in 1940 to 77,716 ounces in 1944 but may be expected to improve with the removal of restrictions imposed by wartime necessity. Gold continues to be washed from placer deposits in the Caroni region near the head of the Yuruari River and its tributaries. The extent of these deposits has never been determined, but in general they are not believed to be individually large enough for dredging operations.

Iron.—In 1939 the Iron Mines Co. of Venezuela, a subsidiary of the Bethlehem Steel Co., obtained concessions centering in El Pao 30 miles south of the town of San Felix. Ore reserves estimated at 60 to 100 million tons of hematite are reported to contain 68 percent

iron and very small amounts of phosphorus, sulfur, and silver. The company has started construction of a mine plant and transport facilities for the daily export of 6,000 tons of ore and hopes to be ready to ship before the end of 1945. The chief obstacle to be overcome is the dredging of a deep channel through the Boca Grande and Yua sand bars at the mouth of the Orinoco, to permit fully loaded ocean freighters to pass down river to the sea.

Nickel.—The International Nickel Co. is showing active interest in a deposit of garnierite at Lorno de Hierro near San Pedros, south of Caracas. Lorno de Hierro is estimated to contain millions of tons of ore averaging more than 2 percent nickel but of a grade possibly too low to be handled by present metallurgical processes.

Vanadium.—Venezuela has never deliberately undertaken or reported the production of vanadium. Nevertheless, the metal in the form of vanadium pentoxide is regularly recovered from flue dust from the stacks and boilers of ships burning Venezuelan fuel oil. Several tons of flue dust are bagged and sold annually by tanker and other ship lines in American ports. The material as marketed contains 12 to 15 percent V_2O_5 .

Asbestos.—The mining of Chrysotile asbestos is being undertaken west of Tinaquillo, State of Cojedes, where Cía. Anónima Minas de Amianto de Tinaquillo has completed a mill with a monthly capacity of 25,000 tons rock intake and 500 tons fiber output. Small tonnages have been produced for several years, and mill operations started during the first half of 1945. Annual production of 6,000 tons of fiber is anticipated.

Diamonds.—Venezuela has two main diamond-producing areas in the State of Bolívar, one including the lower Caroni River and tributaries and the other the Gran Savana at the southeastern tip of the country. The Caroni district usually supplies about one-fourth and the Gran Savana three-fourths of the total diamond output of the country. Venezuelan diamond production first became commercially important in 1937, reached a peak of 34,048 carats in 1942, and dropped to between 22,000 and 23,000 carats in 1943 and 1944. The rise in output was the result of the war demand for industrial stones and consequent high prices. The post-1942 decline is attributable to deplorable working and living conditions in the areas (including shortages and high cost of food), lack of transportation, and the drop in world prices accompanied by cessation of the United States Foreign Economic Administration's diamond-buying program in Venezuela. A favorable future is dependent on possible highway construction to open up the areas, large investments of capital, and revision of Government regulations to permit large-scale mining with mechanical equipment.

Other nonmetallic minerals.—Magnesite is mined at Lomo de Guerra on Margarita Island by Industria Nueva Esparta, C. A. The company produced only 700 tons of crude in 1944, for consumption in its magnesite-products factory in Caracas. Cement and marine salt are also produced for domestic use only.

Coal.—Two coal mines are operated in Venezuela, one near Altigracia in the State of Guárico and the other at Naricual near Barce-

lona. The coal is subbituminous, production is less than 12,000 tons a year, the condition of the mines is poor, operations are hampered by inadequate transportation facilities, and British brick coal or patent fuel from Cardiff can be bought in Caracas cheaper than Venezuelan coal.

Petroleum.—Venezuela is the largest producer of crude petroleum in Latin America and the third largest in the world, exceeded only by the United States and the Soviet Union, and 1944 established a record year in the history of Venezuelan production with an output of 257,045,668 barrels. In western Venezuela 10 fields in the State of Zulia and 3 in the State of Falcon supplied 71.3 percent of the total production, while the remaining 28.7 percent came from eastern Venezuela, with 12 fields in the State of Anzoategui, 6 in Monagas, and 1 in Guarico. On the basis of operating companies, 95 percent of the total was the output of the three leading producers: Creole Petroleum Corp., Mene Grande Oil Co., C. A., and the Shell Oil Co. subsidiaries. The remaining 5 percent was distributed among Cia. Consolidada, the Socony-Vacuum Oil Co., British Controlled Oilfields, Ltd., two subsidiaries of The Texas Oil Co., and the Orinoco Oil Co. The trend continues upward, and production in 1945 is expected to surpass that of 1944.

Seven hundred miles of pipe line in eastern and 160 miles in western Venezuela carry crude petroleum to shipping points on the Orinoco River, the Caribbean Sea, and the Lake Maracaibo area.

Exports.—In 1944 Venezuelan exports of petroleum (90 percent in the form of crude) surpassed all previous records and as usual dominated the export field, representing between 85 and 90 percent of all exports in point of value. Quantities and destinations are presented in the following table.:

Venezuelan exports of petroleum in 1944

[In barrels of 42 gallons]

Country of destination:	Crude petroleum	Refinery products
Aruba.....	101, 596, 980	2, 956, 854
Curaçao.....	76, 128, 153	9, 187, 734
United States.....	45, 258, 928	1, 147, 956
Canada.....	3, 758, 237	386, 074
British Antilles.....	1, 255, 553	1, 205, 504
Canary Islands.....	641, 630	-----
Uruguay.....	413, 718	966, 131
Brazil.....	65, 385	2, 411, 227
Portugal.....	55, 295	-----
Argentina.....	-----	577, 560
Panama.....	-----	128, 643
Fuel to tankers.....	-----	1, 442, 819
Total.....	229, 173, 879	20, 410, 502

Value of mineral exports other than petroleum decreased 14 percent in 1944 from that of the preceding year. Principal items were gold and diamonds.

AFRICA

By FRANK L. FISHER

The review of the African mineral industry for 1944 shows the results of the general continental program to provide raw materials for the Allied war machine. The disruption of their national economy left a definite pattern in the mineral-producing countries, marked by varied inflation, scarcities of imported manufactured goods, an acute shortage of shipping space for civilian supply, labor migration, and shortages affecting the mineral production in some areas, and a general decline in gold production but pronounced increases in production of the metals necessary to the war effort. A trend toward United States manufactured products was evident in 1944 with the increased realization that the United States is the market for African raw materials, at least until European resettlement is complete.

During 1944 the British and Belgian colonies continued aggressive development of their mineral resources, whereas the French, Portuguese, and Italian colonies were relatively inactive in their efforts to promote exploitation of their deposits. The few countries that do not have colonial domination are in regions of unfavorable mineralization.

The mineral industries of Algeria, Angola, Bechuanaland, British East Africa (Kenya, Uganda, and Tanganyika), Egypt, French Cameroons, French Morocco, Madagascar, Mozambique, Tunisia, and South-West Africa were of secondary importance in 1944. No new developments of importance occurred in the mineral industries in the following countries during 1944, nor is their mineral industry of any significance except for some primitive mining of salt and gold: Anglo-Egyptian Sudan, British Somaliland, Cabinda, Eritrea, Ethiopia, French Equatorial Africa (except Cameroons), French West Africa, French Somaliland, Gambia, Italian Somaliland, Liberia, Libya, Rio de Oro, Rio Muni, and Spanish Guinea.

UNION OF SOUTH AFRICA

The Union of South Africa was the major African mineral producer in value in 1944. Gold, diamonds, and coal dominated the production, and exportable surpluses of copper, tin, asbestos, silver, platinum metals, manganese, and chromite were recorded. The search for strategic metals for Allied interests resulted in the accelerated production of beryl, corundum, ochers, mica, optical calcite, nickel, natural graphite, and tungsten, and domestic demand spurred production of titaniferous iron ore, pyrites, antimony, barite, gypsum, fluorspar, mercury, and salt.

The Witwatersrand gold-mining industry, on which the economy of the Union depends, operated on a reasonably stable basis during the year. The general economic strain of war throughout the continent, labor migration, and an abnormal rainfall that flooded several mines contributed to the decline in production. One company discontinued operations during the year, and the Van Ryn Deep, Witwatersrand Deep, Langlaate Estate, and New Modderfontein

Deep mines served notice of their plans to suspend operations in 1945.

The 1944 gold production again led the world with 12,277,228 fine ounces—522,793 less than in 1943.

Optimism prevailed in the gold region with the anticipated development of two new gold fields—the Far West Rand area and the Orange Free State field. Sixteen new gold mines are planned for these fields, involving a capital expenditure of approximately \$320,000,000 in the postwar era. The Orange Free State field, surveyed by a large-scale and well-planned drilling program by various companies since 1937, is 90 miles north-south and 30 miles east-west, with its center at Odendaalrust. Exploitation of both fields will necessitate deep-shaft operations.

Diamond sales of approximately \$70,000,000 in 1944 were less than the 1943 record year. Production, third largest in the world, amounted to 933,682 carats. Coal production continued to increase to 22,590,201 metric tons in 1944. Exports of cargo and bunker coal totaled 3,995,740 metric tons. The Union held its place as third largest producer of platinum and allied metals, with approximately 80,000 ounces for the year.

The bulk of the diamonds, asbestos, and copper was exported to the United Kingdom. The United States and the United Kingdom were the chief importers of the chromite, manganese ore, beryllium ore, fluorspar, mica, and corundum produced in the Union. The coal was exported to countries on the east and west coasts of the continent, the Middle East, Ceylon, Argentina, and Brazil.

BELGIAN CONGO

The Belgian Government need for revenue coupled with the war demand to keep the Belgian Congo mineral production at an accelerated rate during 1944, and the country maintained its position as the world's principal source of industrial diamonds, radium-uranium, and cobalt. Production of copper, gold, silver, tin, tungsten, zinc, tantalite-columbite, cadmium, and manganese was maintained at capacity. Exploration for mineral deposits in the colony has been extensive and thorough, but the possibility of the discovery of new, large deposits is still considered favorably.

Production of diamonds has been estimated at 7,540,000 carats in 1944, a decline from the peak of 9,600,000 carats in 1940. Forminière (Soc. Internationale Forestière et Minière du Congo) is in control of and manages all diamond-mining operations; most of the diamonds come from the Beceka field. Estimates of diamond reserves indicate a potential annual production of 7,000,000 carats of Beceka crushing bort for 14 years and 500,000 carats of cuttable stones for 12 years, with the possibility of an additional 10 years' production of both at the same rate. The Congo continued to supply about 60 percent of the world's cobalt with a production in 1944 of 2,200 tons obtained as a byproduct of the copper production. Operations were resumed at the Shinkolobwe radium-uranium mine in 1944. This mine had been shut down since 1937, the trade being supplied from available stocks since that time.

Trade with the United States has increased from 7.6 percent (\$2,500,000) of the total imports in 1938 to 41.35 percent (\$21,638,000) in 1943. The export trade of Belgian Congo directly to the United

States was approximately \$11,000,000 in 1943. Favorable continuation of this trade in the postwar period is likely, and the United States will be in position to participate to a greater extent than in the past in the further economic development of Belgian Congo.⁹

The bulk of the industrial diamonds and tin are exported to the United States. The copper is refined in the United States and re-exported to the United Kingdom.

NORTHERN AND SOUTHERN RHODESIA

The copper belt of Northern Rhodesia was the British Empire's largest copper producer, with more than 200,000 tons during 1944, and the same region was second to Belgian Congo as a producer of cobalt. The N'kana mine continued to be the major operator and produced substantial quantities of selenium, gold, and silver in addition to the cobalt and copper. The Broken Hill mine contributed important quantities of zinc, vanadium, and lead during the year. Northern Rhodesia also produced minor amounts of mica, bismuth, tin, manganese, and iron ore.

A slight decrease in gold output was noted for Southern Rhodesia during 1944, but the country continued to maintain a production of more than 500,000 ounces of gold and 100,000 ounces of silver. Chromite production exceeded 300,000 tons during the year. The country was the second-largest producer of asbestos, but production statistics for 1944 are not available. Minor production of tin, tungsten, and mica was recorded during the year.

BRITISH WEST AFRICA

Nigeria.—Tin and columbite comprised most of the mineral production in Nigeria in 1944. Tin output was maintained at approximately 1,400 tons of cassiterite per month, and columbite production approached a 200-ton per month average. Efforts to develop the wolframite deposits were not as successful as expected, and production was negligible. About 300,000 tons of coal for domestic consumption were mined during the year. Gold production, mainly by primitive mining methods, was normal. The columbite is exported to the United States and the cassiterite to the United Kingdom.

Gold Coast.—Gold Coast was a major African mineral producer during 1944, with 534,487 fine ounces of gold, 512,528 dry metric tons of manganese ore, 1,167,858 carats of diamonds, and 108,939 metric tons of bauxite. Output of these minerals showed a general decrease from 1943. The colony also produced 56,820 fine ounces of silver and relatively small quantities of iron ore, tin ore, and platinum.

Sierra Leone.—The production of diamonds is the major mineral industry of this country. Output in 1944 was approximately 900,000 carats. The colony also produces gold, silver, platinum, and chromite, but in general the mineral deposits of the colony have not been developed on a large scale.

OTHER COUNTRIES

Algeria.—The Algeria mineral industry was retarded considerably in 1944 as a result of the war. Only iron and phosphate rock were

⁹ A foreign minerals survey on the Mineral Resources of the Belgian Congo is in preparation and is expected to be published during 1945.

produced in exportable quantities. Pyrites and an increased quantity of coal were mined for local consumption, but the production of lead, zinc, and antimony was at a standstill.

Angola.—Production of industrial diamonds in Angola was normal during 1944 with about 786,000 carats. An extensive campaign to secure strategic minerals resulted in a production of 3,860 kilograms of mica and 1,000 kilograms of quartz crystal. Interest was revived in the extensive asphalt deposits, and 4,363 metric tons of rock containing 22 percent asphalt were mined. Gold, sea salt, copper ore, and manganese ore were produced in relatively small quantities.

Bechuanaland.—A small production of gold and silver continued to be the only minerals of economic importance extracted in Bechuanaland during 1944.

British East Africa.—Gold and silver remained the most important minerals produced in Kenya Colony in 1944. Production of asbestos, graphite, lime, mica, quartz crystal, salt, soda, and talc was also recorded. Gold, silver, and industrial diamonds were the significant minerals produced in Tanganyika during 1944, with minor quantities of corundum, mica, salt, and tin. Uganda Protectorate supplied minor quantities of bismuth, gold, mica, tantalite, columbite, tin, tungsten, and beryl in 1944.

Egypt.—The 1944 mineral production in Egypt was confined primarily to nonmetallic minerals, particularly building materials. War conditions temporarily caused a gradual decrease in the production of these products.

French Cameroons.—Tin, gold, and rutile continued to be mined in French Cameroons in increased quantities.

French Morocco.—Phosphate rock remained the most important mineral produced in French Morocco during 1944; output was nearly 1,500,000 metric tons. The country also contributed an important production of cobalt, antimony, lead, asbestos, and gold.

Madagascar.—The principal minerals produced in Madagascar in 1944 were graphite, mica, and corundum in increased amounts. Graphite production was 14,478 metric tons (11,207 flake, 3,271 fines) compared with 12,949 metric tons in 1943. Mica production rose from 343 metric tons in 1943 to 493 in 1944. An expanded demand for corundum by the United States resulted in an increase from 14 metric tons in 1943 to 70 metric tons in 1944. This French colony also had a minor output of gold, coal, beryllium, lead, bismuth, talc, kaolin, and feldspar.

Mozambique.—The significant developments in Mozambique in 1944 were the increased production of corundum, the progress made toward completing the Beira-Tete railroad, which will facilitate transportation from the Moatize coal field, and the granting of an oil concession to Manica Trust, Ltd., of Beira for the most exhaustive oil exploration carried on in the colony to date.

Tunisia.—The return to normal in the mineral industry continued to progress satisfactorily in Tunisia during 1944. Iron-ore output, which had averaged 480,000 tons during the past 19 years, reached 100,000 tons in 1944. Lead attained one-third the normal production rate, and approximately 500,000 tons of phosphate rock were produced during the year. Minor production of zinc, mercury, and coal was also resumed.

South-West Africa.—This country was important in the output of vanadium ore and lepidolite during 1944 and produced over 154,000 carats of industrial diamonds and significant quantities of graphite. It also reported production of beryl, gold, salt, tin, and tungsten.

EUROPE

By BYRON B. McCROSKEY

Throughout 1944 the European mineral industries were confronted with the prodigious task of supplying vast quantities of minerals and mineral products necessary to prosecution of the war. As the year progressed the increased tempo of the fighting greatly accelerated the military requirements of both the United Nations and Germany for these materials.

German economy during the entire year was in a constant state of rapid deterioration that accompanied loss of territory and incessant bombing. The lack of adequate quantities of petroleum and petroleum products was perhaps the most important single factor contributing to the final German collapse. By the end of 1944 approximately two-thirds of its crude-oil resources had been lost. In addition, a large part of its synthetic-oil capacity had been destroyed by bombing. After occupation of the Rumanian and Polish oil fields by the Russians during 1944, German crude-oil supplies were completely dependent on the recently developed fields of Austria, Hungary, and Germany proper. Total production from these sources was estimated at approximately 27,000,000 barrels for the year, or equivalent to about 1.6 percent of the United States 1944 crude-oil production.

As before the war, Hungary continued to be one of Germany's principal sources of bauxite.

Although statistics are not available, it is logical to assume that the Austrian iron and steel industry became vital to Germany, especially after the liberation of France and Belgium and the highly destructive bombing of the Ruhr district.

By the end of 1944 Germany had been forced to evacuate most of the Balkan Peninsula, virtually all of France and Belgium, and the southern part of Italy. The Balkan withdrawal lost for Germany the rich mining areas of Yugoslavia, which were believed to have furnished for a time approximately half of the German new supply of chrome ore, two-fifths of the copper and antimony, and one-third of the lead.

The invasion of France by the United Nations not only deprived Germany of the highly important iron, steel, and light metals industries of France but also severed trade connections with Spain and Portugal which had previously been of strategic importance to Germany as a source of mercury, tungsten, and tin. The loss of this trade was a severe blow to the mineral economy of both countries. Portuguese tungsten and tin production dropped to a fraction of the 1943 output and was brought to a standstill before the end of the year. In Spain the loss of German trade immediately ended the production boom in many of the mineral and mineral products previously shipped

to Germany. Tungsten and mercury were the most noticeably affected, iron ore and lead to a less extent.

Northern Italy, most of the Netherlands, and all of Denmark and Norway remained zones of German occupation throughout the year. Of these countries only Italy and Norway were of significant importance to Germany as sources of mineral supplies. Before invasion by the United Nations Italy was important to Germany as a producer of aluminum, mercury, pyrites, lead, zinc, and sulfur. By the end of the year, however, the principal mercury, pyrite, lead, zinc, and sulfur mines were in the hands of the forces of the United Nations.

Norway's importance as a mineral producer decreased considerably during the year. Estimated aluminum production was 15,000 tons for the year, compared with 27,000 tons for 1943. Although the production of other minerals and mineral products for the first 9 months of 1944 compared favorably with that of the corresponding period of the preceding year, in most instances it was substantially lower than during the prewar period.

Although the Germans throughout the year were trying to obtain from their rapidly diminishing resources sufficient military supplies to continue the war, the United Nations were confronted not only with the problem of greatly increasing their military supplies but also that of restoring the economy of France and adjacent liberated areas of Belgium, Luxembourg, and the Netherlands to a condition that would at least satisfy the minimum civilian requirements. Unfortunately, liberation of these areas was accompanied by a most severe coal shortage. As the economy of these countries depends almost completely on coal, the urgency of immediately obtaining adequate coal supplies, either by increased production or imports, became paramount.

The coal mines of these countries were recovered more or less intact, but owing to the shortage of labor, equipment, and transportation facilities production by the end of 1944 was about only one-half of the normal output. British coal production during 1944 was the lowest for a normal working year since 1892, and the amount available for export was reduced to such an extent that it was impossible for France to obtain quantities of coal, coke, and briquets anywhere near the 5 to 9 million tons per year imported from Great Britain before the war.

During 1944 Russian economy to a large extent was dominated by the tremendous task of rehabilitating that portion of its mining and metallurgical industries situated in the liberated areas. Restoration of the coal mines of the Donets Basin, which before the German invasion supplied more than 50 percent of the country's total coal output, was of major importance. These mines, liberated during 1943, were estimated to be producing by the end of 1944 at the rate of approximately 25,000,000 tons of coal annually—about 30 percent of their prewar capacity. The estimated 30-percent increase in total 1944 coal production over that of 1943 was due largely to the renewal of mining operations in this basin. In addition to the rehabilitating of former producers, numerous new collieries were opened, and several new discoveries were made during the year.

The restoration of the Krivoi Rog iron and the Nikopol manganese mines was started immediately after their liberation in April and May 1944. Although rapid progress was made, the damage to the Krivoi Rog mines was so severe it was estimated that a minimum of

2 years would be required to restore them to normal. Before the war the Krivoi Rog district supplied approximately 62 percent of the country's total iron-ore production. Rapid progress was made also during the year in restoring the Ukraine iron and steel industry to its former productivity.

In a statement made in late June 1944, it was revealed that Russia's annual output of steel was about 12,000,000 tons, that the prewar level had reached 22,500,000 tons, and that future plans were to increase annual production—presumably in two 5-year periods—to 60,000,000 tons.

The vast rehabilitation program in progress during the year was accompanied by expansion of mineral production in areas outside of the devastated zones, opening of new mines and plants, and discovery of new mineral deposits. The growth of the eastern iron and steel industry continued. Coke production was estimated at 11,000,000 tons, of which about 10 percent came from the devastated areas. Oil production was estimated at 275,000,000 barrels for the year—about 27 percent over the 1943 output. Increased production of fluorspar, mercury, aluminum, molybdenum, and other metals and minerals was anticipated, and the press reported new discoveries of molybdenum, mercury, tungsten, and other minerals during the year.

THE MIDDLE EAST ¹⁰

By BYRON B. McCROSKEY

The petroleum industry of 1944 was highlighted by the amazing disclosures made concerning the oil fields of the Middle East, or more specifically the Persian Gulf area. Developments in the area were so outstanding that they attracted the attention not only of the petroleum industry but of the entire world. Perhaps the most important investigation made of the area was that of the Technical Oil Mission to the Middle East, which in its preliminary report,¹¹ published in the early part of the year, revealed proved and indicated oil reserves of 25 to 27 billion barrels for the six countries—Iran, Iraq, Saudi Arabia, Kuwait, Bahrein Island, and Qatar—bordering the Persian Gulf. These tremendous reserves, equivalent to about one and one-fourth times the proved reserves of the United States or about 38 percent of those of the entire world, were the result of an extremely limited amount of exploration work—approximately 150 wildcat wells or less than 5 percent of the number of wildcat wells drilled in the United States every year.

Although the production of the Persian Gulf fields reached about 150 million barrels during 1944, or 34 percent more than in 1938, this increase in no way was proportional to the increased potential value of the region. The refinery capacity of the area was also enlarged during the year to about 500,000 barrels per day. Compared with the 1,677,753,000 barrels of crude oil produced in the United States during 1944, the output of the Persian Gulf fields appears insignificant. However, preliminary plans are to increase the production of the area

¹⁰ Includes Turkey, Syria, Palestine, Trans-Jordan, Iraq, Iran, Afghanistan, and all the countries of the Arabian Peninsula.

¹¹ De Golyer, E., Preliminary Report of the Technical Oil Mission to the Middle East: Bull. Am. Assoc. Petrol. Geol., vol. 28, No. 7, Tulsa, July 1944, pp. 919-923.

to a million barrels per day as soon as transportation facilities are available and markets can be developed in Europe and Asia.

THE FAR EAST AND PACIFIC AREAS

By NELSON DICKERMAN

In 1944 mineral production in the Far East, Australia, and the Pacific islands followed much the same pattern as in 1943. Australia, China, India, and New Caledonia continued to supply the United Nations with vital metals and minerals. Burma, Thailand, French Indochina, the Netherlands East Indies, the Philippines, and Christmas, Palau, Ocean, Nauru, and Hainan Islands remained under Japanese domination, but the Japanese lost control of the shipping lanes from these conquered lands and at the end of the year were able to bring very little of the coveted ores, minerals, and oil to the home islands. Allied armies moved into Burma, the Philippines, and later Borneo and tightened the blockade of Japanese shipping by air, submarine, and naval task forces. While Japan looked to the south for iron, manganese, chrome and nickel ore, bauxite, and tungsten, the United Nations looked to the same areas for tin and rubber which are badly needed. Even after liberation it will be a long time before these areas will be able to supply much rubber and tin.

INDIA

Indian mineral production in 1944 showed a decrease in most lines from that of 1943, due principally to inability of the railroads to handle the heavy traffic, to the congestion of the ports moving military supplies, and to a certain extent to a scarcity of labor in the mining fields. At the beginning of 1944 some 700,000 metric tons of manganese ore were in stock piles, and production was only nominal—about 10,000 to 12,000 tons a month. Imports of Indian manganese ore into the United States were less than 43 percent of the amount received in 1943. Iron and steel production was down except for finished steel products, which were up some 12,000 tons. Coal output increased about 2 percent, but not sufficiently to meet all demands. Petroleum was up about 13 percent. Exports of mica were down more than 30 percent, but ilmenite exports to the United States increased about nine times. The United States also received beryl, futile, and zirconium from India during the year.

BURMA

The Japanese were not able to get much lead or zinc in 1944 from the Bawdwin mine of the Burma Corporation but did obtain enough oil from the Yenangyuang and Chauk oil fields to meet their local needs. As the Bawdwin mine was liberated in the early months of 1945 the British should be able to rehabilitate the mine workings and produce some badly needed lead and zinc in the early part of 1946. Before the war Bawdwin produced some 80,000 tons of lead and 60,000 tons of zinc a year. The oil fields which have now been occupied and which normally produced almost 8 million barrels per year, should be put in commission within 6 to 9 months after oil-well supplies and refinery equipment are provided. This should relieve the burden to some extent on the Persian Gulf tankers.

FREE CHINA

In Free China in 1944 mineral production was disappointing and showed a marked decrease from production in 1943, except for petroleum products and steel, which increased substantially. The decrease was attributed to the loss of territory, especially in Hunan and Kwangsi Provinces, and to inflation which caused much hardship to producers.

The following table presents 1944 production and the percentage change from 1943.

Mineral production of Free China in 1944¹

Mineral:		Production, 1944	Change from 1943, percent
Coal	metric tons	5, 457, 756	-9
Coke	do	260, 026	-31
Copper (refined)	do	185	-76
Lead (refined)	do	646	-45
Zinc (refined)	do	331	-41
Tungsten	do	3, 235	-64
Antimony (pure)	do	203	-52
Tin (refined)	do	2, 195	-50
Mercury	do	103	-13
Pig iron	do	40, 134	-52
Steel	do	14, 391	+97
Crude oil	42-gal. bbl.	504, 701	+13
Gasoline	do	96, 332	+33
Kerosine	do	51, 444	+287
Diesel oil	do	3, 699	+206

¹ Source: Report of U. S. Foreign Service officer, Chungking.

A forecast of improved production in 1945 is based largely on the recommendations of the Nelson Mission to China and on the mission's action in setting up a Chinese War Production Board in November 1944 and providing the assistance of technical specialists. Dr. Wong Wen-Hao, Chairman of the War Production Board and Minister of Economic Affairs, on May 2, 1945, stated that there was a distinct increase in output of 18 kinds of vital metals and industrial products of practical importance in March 1945 over November 1944.

BRITISH MALAYA

Very little information has come out of British Malaya as to activities in tin and rubber production. It is unlikely that the Japanese have pushed either of these industries, as they had plentiful supplies of both and would only encourage production to keep the native population employed.

The British Government is now considering rehabilitation of the tin industry in the shortest possible time after the peninsula is freed. It is unlikely that much tin will be recovered by dredging before the end of 1946 at the earliest, although by providing gravel pumps and Diesel engines for power some may possibly be forthcoming from Malaya not later than 6 months after its liberation. This, with the Chinese workings and a certain amount of tin which has probably been secreted by the Chinese, should help relieve the scarcity of that metal.

JAPAN

In 1944 Japanese mineral production continued at a high rate. The movement of raw materials and goods from Manchuria, Korea, and North China was handicapped by the shortage of shipping created by the sinking of ships by Allied submarines. This was overcome in part by the transfer of more cargo to the railroads on the mainland and the short shiphaul from Korea and Manchuria through the Sea of Japan. The movement of supplies from Malaya, Netherlands East Indies, Thailand, French Indochina, the Philippines, and Formosa became steadily more difficult as the American forces moved westward and especially after landings in the Philippines. This western movement gave the submarines forward bases for their operations, thus increasing their striking power, and also advanced air bases from which planes could take a heavy toll of all Japanese shipping moving north. By the end of 1944 the amount of raw material and oil moving to Japan from the south was only a small fraction of that shipped in 1943. This was not immediately serious for the Japanese war industries as ample supplies had been stored, but it was a warning of what the future offered.

In 1945 Allied forces some 325 miles south of Kyushu and only 400 miles from the Chinese coast cut all direct shipping from the south Pacific, Formosa, North China, Korea, and the southern ports of Manchuria, and reduced the Japanese to total dependence on their stock piles. As bombs continued to destroy the large industrial plants and interrupted rail and road lines, it is possible that for lack of materials some plants may have had to close while supplies were in abundance at other points in the islands. This disruption of supply lines and production facilities led to the collapse of Japan in August.

NETHERLANDS EAST INDIES

Little is known of mineral production in the Netherlands East Indies through 1944. Allied attacks on shipping and the bombing of oil installations and mines undoubtedly cut down supplies to Japan through the latter part of the year.

The Netherlands East Indies, through its Planning and Reconstruction Commission in New York, has set up a credit of 140,000,000 guilders to buy coal and tin-mining machinery, agricultural implements, fertilizers, and consumer goods in the United States. It has also asked quotations for tin dredges to be built in the United States and then towed across the Pacific to Banka and Billiton. The oil fields at Tarakan are now in operation as they are shallow and the fuel oil is of a quality that can be used directly without refining. To some extent this should relieve tanker service from the Western Continent. The oil fields around Brunei, Seria, and Miri in British Borneo are also shallow and undoubtedly will be quickly put back in service. This oil, too, is of a quality to be used directly from the wells with only simple refining.

AUSTRALIA

By F. M. CHACE

Production of metals and minerals essential to the war continued at a high rate in Australia during 1944. Notable increases took place in the production of metallic copper and slab zinc, and output of gold, lead, iron, and coal, although less than in 1943, was still well above prewar levels. Manpower shortages, inadequate supply of mining equipment and supplies, strikes, and other wartime difficulties prevented a higher rate of production.

Production of copper increased from a prewar level of less than 18,000 metric tons annually to approximately 31,300 metric tons in 1944. This increase was due almost entirely to the output of the Mount Isa mine in western Queensland, where lead-zinc mining was curtailed in 1943 so that all efforts could be concentrated on the copper ore body found in the hanging wall of the Black Star lead-zinc ore body.

Although mine production of zinc continued to decrease, the output of slab zinc increased from 77,600 metric tons in 1942 to 80,200 metric tons in 1944. Australian lead output has declined steadily from 274,400 metric tons in 1940 to 172,800 metric tons in 1944.

Owing to industrial disputes in the New South Wales coal fields, production of coal was relatively low in 1944. The recorded output for the Commonwealth dropped from 16,206,000 metric tons in 1942 to 13,958,000 tons in 1944. It was necessary to ration coal to both industrial and civilian consumers.

The Broken Hill Proprietary Co., Ltd., is developing large, high-grade hematite ore deposits on Yampi Sound. The total reserves of Yampi Sound are estimated at 187,000,000 tons to a depth of 500 feet below water level. Work is in progress at Wundowie, 41 miles from Perth, where the Western Australian Government is erecting a charcoal iron plant with a capacity of 10,000 tons a year, which if successful, calls for an increase to 100,000 tons of charcoal iron.

During 1944 and 1945 the Commonwealth and Tasmanian Governments are to spend £A3,000,000 (approximately \$9,750,000) to establish an aluminum-ingot industry in Tasmania, where cheap hydroelectric power is available. Bauxite is available in the Ouse Valley and elsewhere in Tasmania, with reserves totaling about 3,000,000 tons. The project is justified on the grounds of national defense.

The King Island scheelite mine between Tasmania and Victoria produced 190.9 metric tons of concentrates in 1943 containing 65 percent WO_3 . This is one of the largest scheelite deposits in the world, with a reserve of over 1,117,655 metric tons containing 0.70 percent WO_3 .

Tantalite produced at Wodgina and Greenbushes, Western Australia, and exported to the United States in 1944 contained 9,315 pounds of tantalum. The ore averaged 50 percent Ta_2O_5 . Mining of beach sands containing rutile, ilmenite, and zircon along the New South Wales-Queensland coast continued at an accelerated rate. Imports into the United States were: Ilmenite concentrates 158,605 pounds, rutile concentrates 3,516,000 pounds, zircon con-

centrates 43,400 pounds, and beryl 1,035,683 pounds containing approximately 10 percent BeO.

Gold production continued to decline. Western Australia dropped from 1,191,428 ounces in 1940 to 464,440 ounces in 1944; and output in Victoria from 180,567 ounces in 1940 to 56,512 ounces in 1944.

Water supply continues to be a serious problem to Australian mines. In the Broken Hill lead-zinc-silver district arrangements were made to bring in water by rail from the Darling River at Menindee. In March 1944 a 223-mile pipe line was completed from the Murray River on the Victoria-South Australia Border to Whyalla on the west coast of Spencer Gulf in South Australia. Whyalla is the center of a new and expanding steel industry, close to the major iron-ore fields at Iron Knob.

PHILIPPINE ISLANDS

With the Philippines liberated, the question of future American participation looms large. The Japanese did not work the gold mines but robbed them of much equipment, some of which was taken to the Lepanto copper mine at Mankayan in Mountain Province. By extensive development this mine, which produced some 7,500 tons in 1941, was thought to have furnished the Japanese with some 30,000 tons of copper a year. The Japanese also took stocks of manganese and chromite which were left at the mines but did not work these or the iron mines to any extent.

American holdings in the islands are large, but many of the buildings, plants, and mines have been destroyed or robbed by the invaders. To restore the islands to a postwar position of independence, in fact as well as politically, will require a large investment of capital and goods.

With the Philippines to receive their independence in 1946 and the Tydings Mission recommending a large grant of money to restore the islands' economy as well as extending the free entry of goods to both countries over a longer period than was set in the first Independence Act, the American position should have a great advantage over other nationals trying to enter that field.
